Volume 254   March 6 1975

Guide to authors

● Articles are up to 3,000 words in length with at most six displayed items (figures and tables) and may either be reports of major research developments in a subject or broader reviews of progress

● Letters are brief reports of research of unusual and wide interest, not in general longer than 1,000 words, at most they have three or four displayed items (figures and tables)

● 'Matters Arising' permits occasional short discussion of papers that have previously appeared in *Nature* There is a limit of 300 words

Manuscripts may be submitted either to London or Washington Three typed copies should be submitted, each including lettered copies of figures Typing (including references) should be double spaced The title should be brief and informative Pages should be numbered References, tables and figure legends should start on separate pages Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends Units should conform to the Systeme International Greek characters should be identified in the margin on their first appearance Equations should occupy single lines if possible, exp (a) is preferred to e^a if 'a' is more than one character Articles should be accompanied by an abstract of not more than fifty words listing the main conclusions

References are indicated by superscripts in the text See any contemporary *Nature* for style, but note

(i) To refer to several references by the same author at once, only one reference number need be given

(ii) Cite first and last pages

Abbreviations should follow the *World List of Scientific Periodicals*, fourth ed (Butterworth, 1963-65) Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references Their publisher and place of publication should be clearly indicated 'Personal communication' and 'unpublished work' should be incorporated in the text

Artwork should be sent with the manuscript All artwork should be marked with the author's name Line drawings should preferably be in Indian ink on heavy cartridge paper, although other materials are acceptable, thin, shiny, folded, torn or heavily handled material should be avoided Matt rather than glossy photographs are preferred Figures are usually reduced to one column width The originals should be about as wide as a page of *Nature* Figures, particularly maps, should contain nothing but essential material It is preferred that the original be unlabelled, but with a copy containing lettering Labelling on photographs should if possible be avoided entirely We are always glad to see artwork for possible use on the cover, whether or not it is associated with a manuscript, but cannot guarantee the return of material

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish

A fuller guide appeared in *Nature* (246, 238, 1973)

Cambridge University Press

Crop Physiology
Edited by L. T. EVANS

Comprehensive and perspective reviews of the physio-logical basis of yield in nine of the world's most important crops, specially written by an international group of authorities on those crops This book presents a distillation of the knowledge and experience of those authors and not only provides an important source book for plant breeders, physiologists and agronomists but will be of interest to anyone who wants to know more about the problems of crop yield in the plants that mankind still depends on so heavily

£8 00 net

The Shoot Apex and Leaf Growth
R. F WILLIAMS

This book is a comprehensive and quantitative study of the shoot apex and leaf growth This major study will become a standard work and botanists, particularly those studying plant physiology, crop science developmental biology and theoretical biology will find this stimulating book has much to say that is new and of permanent value

Also issued in hard covers

A new students edition

Chemistry: A Structural View
Second Edition
D. R. STRANKS, M. L. HEFFERNAN, K C LEE DOW, P. T. McTIGUE and G. R. A. WITHERS

A reprint of this established textbook for students in their final year at school or first year at college or university By keeping to one colour throughout the text, it has been possible to publish this as a cheap students' edition

Paperback £3 15 net

Also issued in hard covers

Thermal Vibrations in Crystallography
B. T. M WILLIS and A W PRYOR

This book is concerned with the atoms in a crystal which undergo continuous thermal motion about their equilibrium positions The crystallographer must use concepts drawn from lattice dynamics in order to account for the effect of this motion on experimental measurements
Crystallographers and other scientists interested in diffraction work will find this book particularly useful, and the first part is also suitable reading for under-graduate students in physics and chemistry

£9 50 net

Regular Complex Polytopes
H M S COXETER

This fascinating book is concerned with the properties of regular solids and will appeal strongly to the mathe-matically inclined whether they be professionals students or amateurs Professor Coxeter introduces his reader to many newly discovered generalizations and demonstrates unexpected relationships and con-cepts from various branches of mathematics including magic squares, frieze patterns and kaleidoscopes

SCIENCE COLLEGE

Organochlorine Insecticides

Persistent Organic Pollutants
edited by F. Moriarty

May/June 1975, xii + 302 pp, £7 90/$21 00   0 12 506750 X

This book represents an attempt to indicate the general principles which will help to predict and control events, and to pinpoint the important gaps in our knowledge   While the range of topics covered is wide from analytical chemistry to possible legal and economic restraints, with the major emphasis being placed on biological effects and responses — attention is restricted to persistent organic pollutants, and in particular to the organochlorine insecticides which are by far the most studied   The ideas that are proposed will however apply to a far wider range of pollution problems

Fluid-bed Heat Transfer

Gas-fluidized bed behaviour and its influence on bed thermal properties
J. S. M. Botterill

May/June 1975, x + 300 pp, £9 00/$23 75   0 12 118750 0

Gas-fluidized beds have extremely desirable heat transfer properties, though in industry they have been comparatively unexploited for these specific advantages   This volume, based on the author's past and present work, describes the range of behaviour encountered in gas-fluidized systems and shows how this results in the beds' advantageous thermal properties

The work, dealing with a subject in which there is still scope for experimental investigation, will provide much-needed information for engineers and applied scientists working in the chemical and fuel industries, the metallurgical industry and areas of mechanical engineering   At the same time it will prove of value to those in the food processing industry and to all with an interest in fluid particle systems

Scandium

Its Occurrence, Chemistry, Physics, Metallurgy, Biology and Technology
K. A. Gschneidner, G. T. Horovitz (Editor),
G. A. Nelson, H. H. Schock and D. H. Youngblood

April/May 1975, approx 600 pp., approx. £12 00 /$31 75   0 12 355850.6

This encyclopedic work about one chemical element, compiled by experts in various scientific fields, has a considerable scope ranging from simple chemical reactions to metallurgy and applications   The volume brings together important research developments and original data from various sources, and will also have great value as a reference work where a critical analysis of published literature has been made   The book is interdisciplinary, and is therefore aimed at a wide audience including research workers in rare earth metals, postgraduate students, specialist chemists, physicists, metallurgists, biologists and geologists

Structure of Metallic Catalysts

J. R. Anderson

May/June 1975, x + 468 pp, £12 80/$33 75   0 12 057150 1

This is the first book which attempts a coherent account of the structure of metallic catalysts, in particular the author tries to relate general preparative methods and ultimate structure to the chemistry and physics of the materials concerned

Contents Introduction to metals and catalysts   Support materials   Massive metal catalysts   Dispersed metal catalysts   Structure and properties of small metal particles   Measurement techniques surface area, particle size and pore structure   Measurement techniques   surface composition and structure   Appendix 1   Data for metals   Appendix 2   Illustrative recipes for the preparation of metallic catalysts, Subject index

Effects of Interferon on Cells, Viruses and the Immune System

edited by A. Geraldes

June/July, xii + 662 pp, approx. £17 00/$43 25 0 12 280650 6

This book is based on the proceedings of the Gulbenkian Institute Symposium on interferon, to collate information on fundamental problems regarding mechanisms of induction and action and their regulation   The book discusses many major breakthroughs, and reviews the present state of interferon research   A considerable amount of emphasis is placed on the action of interferon on cell metabolism, its depressing influence on the immune system, and its subsequent effect on grafts   Other progress is represented by contributions on the antiviral effect of Sepharose-bount interferon, interferon messenger RNA, and the genetic regulation of the interferon system   Focusing attention on aspects of a new phase of interferon research, this volume will excite interest among biologists, biochemists, virologists, immunologists and those involved in medical research.

March 6, 1975

Who makes the decision on life and death?

Thou shalt not kill; yet needst not strive,

Officiously to keep alive.

Arthur Hugh Clough's witty Victorian Ten Commandments for the comfortable sometimes have a very modern ring to them—none more so than the sixth when put in the context of modern medicine. Last week BBC television gave us two looks at spina bifida; the first was an hour-long documentary of great distinction which managed at once to educate, to convey a message of hope, to present the caution of scientists in an understanding light and to provoke on the question of whether severely handicapped babies should be left to die. The second took up the running on this last issue in the programme "Controversy", and Dr John Lorber, who is one of many pediatricians who give parents the chance to withhold treatment in bad cases, was confronted with two doctors and a theologian who believed this option should not be given, and an audience which seemed (at least after editing) to divide roughly equally; it's tantalising that the producers of "Controversy" don't ask for a vote, even after the formal ending.

It was no great surprise that the parents at the debate provided the most emotional and memorable contributions, nor that the lady from the National Secular Society should have said what she did about terminating more lives. Somewhat suprisingly, the theologian Professor Gordon Dunstan, stated the case for preserving life in muted terms: let them die and you reduce the capacity for heroism and the incentive to medical science. For the rest, the debate rested fairly inevitably on the technical data and philosophies of different doctors.

And yet one thing did emerge with remarkable clarity —that it is the doctor, not the parents who makes the decision whether the child lives or dies. If the doctor believes severe cases should be allowed to die relatively peacefully then he will be capable of convincing almost all his clients to follow this course. If, on the other hand, he believes severe cases deserve every attention that medical science can bestow, he will be able to take parents along with him in that direction.

There is nothing new in all this. In the matter of birth control and abortion, sophisticated women have recognised for many years the necessity for pre-selecting the person whom they consult.

The reason that the doctor has so much power in the decision-making process is not simply that he has immense knowledge where his client has none—after all, the decision that the parents have to make is one in which technical knowledge is only one ingredient. Rather,

the parents must be only too aware that if the doctor expresses a view one way and they choose to ignore his opinion, they have to live not only with their own decision but with the doctor himself for months if not years. It is presumably for the same reasons that people don't more often pick arguments with teachers, bosses and dentists.

Dr Lorber has broken valuable new ground by publicising a new option for parents so courageously (although the point was made in the programme that doctors do occasionally confront comparable problems in other circumstances). Many have, and will, object to the granting of the option on grounds that there are possibilities that the child could live a happy life, but it is striking how little public uproar there has been on grounds of morality; it must be that the obvious detached sincerity with which many parents have elected not to support their child's life, and the frequent damage to family life—even culminating in suicide—that spina bifida can bring, prevents some of the more conventional sanctity-of-life responses that one would otherwise expect. But how do we ensure that it is truly an option, and for that matter that the option is available to those that need it, regardless of the hospital area in which they happen to live?

However carefully the doctor may present both sides of the case it is inevitable that his clients are strongly influenced by the slightest hint of a preference one way or the other, and the choice which was originally theirs has subtly been surrendered to the doctor. In many cases this may be no bad thing, but this does not necessarily justify continuing a procedure in which some clients may eventually look back in some puzzlement at how they reached a particular decision. Offering a second opinion does not seem a good safety net; few seek it, and although doctors may claim this is because clients can come to their own conclusions, it may equally indicate tentativeness of clients in the face of medical men.

An idea worth consideration is that the medical profession, or even some organisation outside the profession, should provide a new sort of service to doctors and clients in such circumstances. Someone without any involvement in an individual case should be deputed by the doctor to present the options to the client, proffer advice if requested and then convey the decision to the doctor. In this way not only would it be clearer that the decision has been made by those who must ultimately bear the responsibilities, but also there would be assurance that the range of options discussed reflects all medical possibilities. ∎

Huxley remembered

SIR JULIAN HUXLEY, FRS, one of the best known scientific personalities of our day, died in London on February 14 at the age of 87.

Huxley was a King's Scholar at Eton and went on to Balliol, Oxford, where he became Brackenbury Scholar and, from 1910–12, a lecturer in zoology. As a undergraduate, he was also awarded the Newdigate Prize for Poetry. At 25, he became Professor of Zoology at the Rice Institute in Houston, but at the outbreak of war returned home and joined the Army Intelligence Corps, serving at the Italian front when the armistice was signed. He returned to Oxford in 1919 as a Fellow of New College and Senior Demonstrator in Zoology, and in 1925 was appointed Professor of Zoology at King's College, London. He also held the office of Fullerian Professor of Physiology at the Royal Institution from 1926–28, but resigned both scientific posts to devote more time to writing and research. His association with the Zoological Society of London as Secretary began in 1935 and lasted until 1942, during which time he helped to develop Whipsnade Zoo. His lifelong interest in Africa resulted in his being a member of the committee of Lord Hailey's 'African Survey' from 1933–38, and a member of the 1944 Committee on Higher Education in West Africa.

Because of his experience and powerful interest in the problems of social evolution and education, the British government persuaded him to become the first Director-General of UNESCO in 1946.

His many publications on animal behaviour, evolution and genetics are too numerous to mention. His *Problems of Relative Growth* (1932) was a turning point in the study of differential growth of parts of the body, and *Evolution, the Modern Synthesis* (1948) remains the most comprehensive modern work on this subject. But beguiled audiences of the BBC's 'Brains Trust' programme will remember him best as one of the original panellists, and particularly during the Second World War. Huxley also lent his support to many other institutions—the British Humanist Association, the Family Planning Association, the Nature Conservancy, and so on.

Recognition of his work came from all sectors. Among many were the Kalinga Prize (1953) for popular science writing, the Darwin Medal of the Royal Society (1957) for contributions to the study of .evolution, and a Knighthood in 1958. •   □

JULIAN HUXLEY was only a decade or so older, but he was one of my 'heroes' from the time (1921) when I was starting research in chemical embryology. I never knew him really well and never spent very much time with him, but he was always there as a kind of leading figure "amidst the encircling gloom"; and occasionally our lives impinged strongly on each other. In the 1920s he was perhaps best known for his work at Oxford on the hybrid control of amphibian metamorphosis. This was outside my field, as I never worked in classical endocrinology, but when the 1930s came I was extremely interested in Julian's book on heterogony (or heterauxesis, as it afterwards came to be called) *Problems of Relative Growth*. Together with Georges Teissier in France I spent a good deal of time in applying these conceptions to the relative growth of the chemical constituents of animal bodies. This turned out to be one of those lines of of investigation which, though interesting in themselves, do not lead immediately to anything further. Quite different was the situation with Julian's *Elements of Experimental Embryology*, which he wrote with G.R. de Beer in 1934. This was at the beginning of the story of embryonic induction: based on

the fundamental experiments of Spemann and his collaborators, it set the stage for a vast amount of work on the 'morphogenetic hormones'. Terminologies change, and organisers today might be called 'semantophore macro-molecules', but although such great advances have been made in the study of the hereditary 'books of instructions', the nucleic acid chains, it seems that still today it has not been possible to identify the molecules which pass from cell to cell and determine specific differentiation destinies. Doubtless messenger RNA is in the picture somewhere. In any case Huxley and de Beer was a stirring overture to a field of experimental morphology still of the highest importance and fascination today.

But neither Julian Huxley nor I were spirits circumscribed by the walls of the laboratory. Both of us were interested in philosophy, religion, artistic creation, history and literature; both of us, like Charles Sherrington and many other scientists, were moved to write poems from time to time. We must retrace our steps, for *Religion without Revelation* came out in 1927: while my *Sceptical Biologist* was 1929. Of course our standpoints were rather different, though both in a way syn-

cretistic Julian upheld the family tradition of agnosticism and what came to be called 'humanism', while I was for accepting the practice of all the forms of human experience while not granting absolute validity to any of them Consequently I retained liturgical religion and was content to be described as a left-wing Christian socialist —but all this never came between us, and on a great many matters we saw closely eye to eye It was rather like an experience I once had with Fred Hoyle The Cambridge Union proposed to _debate that "wherever science advances religion recedes", and he was to be the proposer, while I was cast as the opponent So we had tea together, and concluded, after carefully looking into it, that there was just that hair's breadth of difference between us as to make the affair possible It was rather like that with Julian and me

But politics kept on breaking in Over a couple of decades, centering on the 1930s, the "Younger Scientists" became a label as political as the "Young Turks" had been in an earlier time Here the essential crux was the relations of science and society, what really were they in the liberal democratic, bourgeois, capitalist society that we all knew, what had they been in the societies of the long-past world, and what could they be imagined to be in socialist society, whether nascent as at that time in the USSR, or more ideally foreseeable in future socialist societies? This movement of the 1930s was the lineal ancestor of such bodies as the British Society for Social Responsibility in Science today, with the big difference that present leading men, such as Joseph Rotblat and Stephen Rose, are contending with a world of nuclear power and nuclear weapons in which the problems of pollution have come much more into the foreground than they were in the 1930s But in those days you had a very powerful group, of which perhaps Julian Huxley and J B S Haldane were the oldest, including Conrad Waddington, Desmond Bernal, Lancelot Hogben, Dorothy Crowfoot and Hymen Levy Other scientists were radical, though not on the left, such as Cyril Darlington and John Baker, while others yet again, like Patrick Blackett and Solly Zuckerman, so phrased their sociological beliefs as not to lose touch with the 'corridors of power' and the establishment, thus retaining a chance of influencing national policy All these 'elements', *quorum pars minimus fui,* met together from time to time in the "Quots and Tots", a dining club in London which was only extinguished by the Second World War Needless to say, it took its name from the phrase *quot homines tot sententiae,* but in fact throughout the 1930s there was a real consensus of agreement among the "Younger Scientists" Their *pronunciamientos* constantly enraged the older generation entrenched in Burlington House, where so strong was the prejudice against scientists doing anything other than science, that I was reduced (though I do not think Julian ever was) to adopting a pseudonym for some of my extra-scientific writings Some may remember that in allusion to certain extremely distinguished officers of the Royal Society, the "Younger Scientists" were accused of riding roughshod over hill and dale

Subjects like animal behaviour and bird-watching were always closed books to me a side of Julian that I never knew Our orbits came into the closest conjunction, however, after the foundation of UNESCO in 1946 I always thought it was Ellen Wilkinson, not R A Butler as has recently been said, who nominated Julian Huxley as the first Director-General, at any rate I was far away in China at the time I had been one of those who throughout the last years of the war had made great agitation to get science included with education and culture in this new specialised agency of the United Nations And it was therefore the greatest of pleasures to get a cable from Julian (I forget whether it was in Chungking or Nanking) asking me to return at once to head up the Natural Sciences Division I duly came, we established ourselves in a large, gaunt, empty house of ambassadorial character in Belgrave Square, and the recruitment of staff went merrily on The UNESCO years brought me into very close touch with Julian and that was the time I got to know him best In those days UNESCO officials were not bound down by too much red tape, as happened later, for example when the Naples Marine Biological Station was about to close down, as its seawater pumps had worn out, a couple of telephone calls with Stafford Cripps elicited that there were plenty of American surplus pumps on the quayside in that very city, and these could be used to keep things going Or again, as soon as we knew that the Poles had lost, during the war, all their printing machines capable of setting up mathematical equations, Julian and I by a couple of telephone calls could get some new machines moving on their way to Warsaw

The UNESCO period, fortunately, found Julian Huxley in one of his periods of most frenetic energy and activity Our daily conferences were unforgettable, with André Thomas Thomas for culture, and Kuo Yu-Shou for education Dear Dr Kuo, I had known him a long time before when he was Commissioner of Education in Szechuan Province Those were the days when we formulated between us many a policy for which afterwards, indeed for the rest of his life, Julian Huxley did great propaganda work— the liquidation of illiteracy, the control of population increases, and the reproduction of great classical spiritual books in many languages other than those in which they were originally written Some of these enterprises have prospered remarkably through the years—for example the international understanding inculcated by the *UNESCO Courier,* which appears all over the world in many languages, or again the UNESCO *History of the World* Julian used to maintain that this was originally my idea, but I feel quite certain that it was his, and all I did was to back it up through thick and thin at various meetings, including those of the Executive composed of the delegates of all the member states This work in many volumes must now be in school libraries all over the world and really may be said to be fairly free from nationalistic prejudices Thomas, Kuo and I were very close to Julian, and only Thomas carried on for any length of time after the first change of Director-General Besides, there were not only the meetings but also very companionable walks and meals on Sundays in the forests of Fontainbleau and Rambouillet where we could compare notes *ad lib*

Finally, in a last act, as it were, Julian and I enormously enjoyed investigating Amerindian archaeology on the occasion of the Second General Conference of UNESCO in Mexico City Together we scoured the wonderful National Museum, visited unforgettable sites, like Teotihuacan, Xochicalco and Chichen-Itza, and sat at the feet of Mexican scholars and writers like Alfonso Caso, Miguel Covarrubias and Alberto Ruz-Lhuillier All this bore much fruit for me later on when in the fourth volume of *Science and Civilisation in China* I had to face the problem of pre-Columbian culture contacts across the Pacific from East Asia

Julian Huxley was a man for whom nothing human was foreign, one thought naturally of the phrase *nihil humanum me alienum puto* He was blessed beyond measure by his marriage with Juliette, happy essentially from beginning to end, right from the day when her father's *vignerons* took Julian to be Oexle—*le type qui a inventé les dégrés* All their friends think of her with the deepest affection, and hope that knowledge of this may moderate, even in however small a way, the sense of loss from which she, like us, is assuredly suffering ☐

Joseph Needham

Huxley : the presence of the 'S' in UNESCO is largely due to him

JULIAN HUXLEY was the leading experimental biologist of his day at a time and in a place in which the ever more detailed validation of the concept of evolution was still thought of as the principal task of biology The supplanting of comparative anatomy by what everybody came to call 'experimental biology' is a fascinating episode in the history of ideas In the early days of the Darwinian revolution the elucidation of homologies and the working out of family trees had the same kind of appeal and confident self importance as molecular biology has today, and I know from personal conversations with him that E S Goodrich, the former Linacre Professor of Zoology and Comparative Anatomy at Oxford and the only British comparative anatomist of the same stature as Gegenbaur and van Wijhe, still regarded himself even quite late in life as a torchbearer and adventurous pioneer of the great new doctrine

But, alas, comparative anatomy became an abuse and an impediment to progress, just as comparative physiology became in the next quarter of a century and as molecular biology will surely become in 10 or 20 years (for I foresee clearly a time when, regardless of what major problems in biology remain to be attended to, the sequencing of a protein will still be regarded as an intrinsically meritorious activity which will be taken to represent the courageous holding aloft of the banner of what was once a great revolution in biological ideas)

Because of his intellectual vitality and the great compass of his interest and understanding Huxley rightly earned for himself the position of acknowledged leader of the newer biology Certainly nobody since has made contributions of comparable magnitude to fields so diverse as ethology (his papers on the courtship behaviour of the great crested grebe are acknowledged classics), physiological genetics, developmental physiology including the study of allometry or differential growth, and ecology, especially in relation to speciation

And then again, Huxley was, as his grandfather had been, a great expositor of the notion of evolution, although sometimes his ideas on the subject were felt by his juniors, rightly or wrongly, to be wrong-headed—mainly because Huxley never really mastered the modern population-dynamical approach to evolution theory, and so great was Huxley's enthusiasm for the idea of evolution that he came in his later years to treat evolutionism as a sort of secular religion

Huxley was a great tutor in the old

Oxford style, a man who, because he loved it, chose to teach the whole of his subject instead of teaching only the parts of it that interested him and for the remainder farming out his students to specialists in other fields The influence of a really good tutor lasts through many generations of pupils, pupils' pupils and so on It is pleasing therefore to reflect that through a lineage which can be worked out with names and dates in detail, Julian's son Francis was his own great grand-pupil (The lineage is Julian Huxley–Gavin de Beer–J Z Young–P B Medawar–Francis Huxley)

With these qualities of character it is not at all surprising that Huxley was kind and helpful to the young, for although people in his position are bombarded from all quarters of the Earth by manuscripts of which the authors profess to seek their recipient's candid opinion, Huxley bore with this kind of imposition very handsomely and often made the time to answer his correspondents at length—sometimes in his own handwriting

I do not know and cannot imagine any scale of evaluation of scientific merit along which Huxley would not stand out as one of the foremost biologists of the 20th century ☐

Peter Medawar

THE contribution that Julian Huxley made to the work of UNESCO in the field of science was remarkable and, in several respects, decisive

In the first place, he fought to ensure that science was given a place among the organisation's concerns on an equal footing with education and culture Thirty years ago, when the conference convened to adopt the Constitution of UNESCO was about to meet in London in November 1945, the issue was still in the balance On one side, the followers of the classical humanist tradition thought it better to deal only with education and culture, since they both centred on the preservation and development of moral values On the other, some scientists took the view that science had become far too complex as an intellectual and social activity, and too important on account of its practical applications, to be only one of the fields of competence of an institution, they looked for a distinct organisation solely and totally concerned with science Huxley was one of those who checked these separatist tendencies The presence of the 'S' in UNESCO is largely due to him

Had the organisation restricted itself to dealing with education and culture,

it would have been no doubt easier to manage, with probably a greater immediate efficiency But none of the difficulties encountered outweighs, in my opinion, the paramount advantages and significance of the existence of an organisation which embraces, through the inter-relationship of its various fields of competence, the comprehensive unity of the minds as a whole

Once this inter-relationship of education, science and culture was adopted as the fundamental principle of UNESCO, no one could have been better qualified than Huxley, with his manifold gifts, varied experience and wide-ranging earlier ventures, to provide the framework of the new organisation's programme And that was the main task to which he devoted the best of his energies and abilities, as Secretary-General of the Preparatory Commission (1946) and thereafter as the first Director-General (1946–48)

In the field of natural sciences, with the help of Joseph Needham, he devoted special attention to the restoration and reshaping, in collaboration with the International Council of Scientific Unions (ICSU), of the international scientific community which had been shattered by the war But Huxley was no less interested in the social sciences, which he thought should have a part to play in all sectors of UNESCO's activities Thus, he put an ethnologist in charge of the first 'fundamental education' pilot project in Haiti His efforts to bring together scientists, educationists and users of the mass media in a wide-ranging movement for the modernisation of science teaching and, more generally, for the popularisation of science, provides another instance of his multidisciplinary approach to problems

Science for him was not merely a body of knowledge and skills, it was the most advanced form of culture, the very basis of all values This feeling of the close kinship of science and culture suggested to him the idea of a *History of the Scientific and Cultural Development of Mankind* He put the proposal to the General Conference at its first session in 1946 and succeeded—though not without difficulty—in securing its adoption And after he had relinquished his functions as Director-General he played a very active part in carrying it out as Vice-President of the International Commission which had the editorial responsibility for the work

One final aspect of his contribution to UNESCO's science programme which deserves special mention is that he wished the organisation to foster among both governments and the

general public a better awareness of certain major issues affecting the future of mankind With his biological background and his evolutionist approach, he was admirably equipped to understand such problems and put them in perspective In matters concerning the preservation of nature and its ecological balances, the proper management of the resources of the biosphere, the quantitative and qualitative implications of population growth, and the problems of human settlements, the views and the programmes that Julian Huxley recommended to UNESCO were a quarter of a century ahead of the ideas of the time They showed a remarkable perception of the true mission of international organisations, which we are now just beginning to discover That mission is not simply to help member states in solving their particular problems It is above all to bring the people of the world to understand the vital problems of mankind as a whole, which require for their solution a sense of togetherness and the joint efforts of the community of nations □

René Maheu

By the death of Sir Julian Huxley we lose not only a distinguished scientist but a man with whom it was as easy to talk of art or literature as of biology I met him first, I think, in 1921 in the exciting society at Garsington, where he and his wife were staying with Lady Ottoline Morrell

At that time Huxley was a Fellow of New College and Senior Demonstrator in Zoology at Oxford Though about as much archaeologist as biologist, I attended his course on genetics In the practical classes which accompanied it we studied the inheritance of eye colour in a small superficially shrimp-like animal, a species of *Gammarus* Chancing to make an unexpected observation which seemed to open up certain possibilities of general interest, I discussed the matter with him In a flash he saw the point and greatly extended my ideas in our subsequent talks and in our delightful excursions to Plymouth to study the animal in its natural habitat and to obtain further material for our investigations He, already a well known scientist, and I, an unknown undergraduate, at once started to research together Our first account of that work appeared in *Nature* in 1925, and we published extensively on it in the next few years And here I would stress a quality entirely characteristic of Julian Huxley When we published our major article (in the *British Journal of Experimental Biology*), giving a detailed account of our results with the conclusions to be drawn from them, it appeared not under

the names of Huxley and Ford but of Ford and Huxley It has been a lesson to me all my life to encourage and give priority to my junior colleagues

This seems to have been among the last pieces of experimental work in which Julian Huxley took part His scientific writings, extending over many years, have been of fundamental importance, his success as Secretary of the Zoological Society of London, and as Director-General of UNESCO was outstanding and needs no encomium from me I would, however, like to draw attention to his greatest and least recognised achievement

In his position, he was frequently visiting universities and scientific institutes of various kinds He would talk to those researching there and from this something unprecedented would emerge He would encounter those who had, perhaps for months or years, been devoting their time to some biological problem of which, often enough, Huxley would know very little In a short conversation he would almost invariably be able to throw a new light on it, and those who talked with him felt that his visit had been an outstanding occasion It was a contribution to science of a most unusual and unselfish kind, one which only a genius could make He obtained little recognition for it, but its cumulative effect was great and can never be assessed

It is difficult to impart an idea of Julian Huxley's friendship It can, perhaps, be comprehended in this He would always speak of a friend better behind his back than to his face few indeed deserves such a tribute □

E. B. Ford

Julian Huxley was a great teacher, and not only in the early academic phase of his career The extent of his influence on zoologists of my own and younger generations is not always realised

He was a leader of the movement which gathered so much momentum in the early 1920s, away from conventional comparative anatomy and the construction of evolutionary family trees to experimental embryology, genetics, comparative physiology and functional analysis In 1923, with Hogben, Crew and J B S Haldane, he launched the Society for Experimental Biology and its journal, then called the *British Journal of Experimental Biology*, Hogben has described the quartet as the Founding Fathers of the society —and the society has done more to guide the development of biology and of young biologists in this country in its half century of thriving expansion than any other

My association with Julian was closest in the late 1920s, when we col-

laborated with my father, H G Wells, in writing *The Science of Life* This was conceived by H G as a companion to his earlier *Outline of History,* to set down plainly and clearly "everything that an educated man—to be an educated man—ought to know about biological science We three got together in 1927 and we made a scheme that covered every division of our immense subject We worked very harmoniously throughout and, after a part publication, produced the book in 1930 " My quotations are from H G's *Experiment in Autobiography*

Those were strenuous years Julian has written in considerable detail about *The Science of Life* in the first volume of his *Memories* (1970), and told how the harmony of the three authors was occasionally obscured by superficial dissonance Most of the text was first written by Julian (who produced far the greater portion) and myself H G's functions were to edit what we wrote and to drive us on to write it There were times of special stress in 1929, when the first of the fortnightly parts were published while others were in page proof, others in galley, others in typescript and some even in the planning stage H G was never an easy man to work with, as many tempestuous episodes in his life reveal, and he could be furious when his collaborators failed to deliver their copy as soon as he wished, or wrote at much greater length than had been planned But the storms soon subsided, in Julian's words "H G lost and recovered his temper, and so did I, but on the whole the atmosphere was gay and friendly" I am sure that the violence of H G's storms was lessened, partly by his great respect for Julian's store of vivid and accurate information and partly by his realisation that he himself was being educated He had studied under Julian's grandfather at the Royal College of Science, now he was learning from the grandson how far and how excitingly the subject had evolved since those days

In any event, the book was written and widely read, appearing over the years in several editions and revisions and in several languages In Julian's own assessment, "The work was indeed an important achievement It is now out of print but its effects are still manifest in the increased space allotted to biology in the educational curriculum, and the greater interest of the general public in biological facts and their consequences " What he does not say is that the work would never have seen the light had it not been for his enthusiasm, his great abilities, and, as I have hinted, his fundamental friendliness and generosity □

G. P. Wells

international news

FUTURE historians of science may well record that a highly significant event took place in a California state park between February 24 and 27, 1975 Meeting at the Asilomar Conference Center here for three days of intense—and at times heated—discussions, 140 scientists from 16 countries agreed that strict controls should be placed on an exciting new technique which enabled genes from one organism to be transplanted directly into another

This attempt at self regulation by a group of scientists is believed to be without direct precedent, for although restrictions have been imposed on research before, they have usually resulted from concern over the uses to which science will be put, or from public pressure In this case, however, the call for controls has come from the very scientists most actively engaged in the research and it has come at the inception of a new field of study, before any known hazards have arisen

Although the genetic transfer technique promises revolutionary advances in molecular biology, the conference decided that its use should be tightly controlled because the genetically modified organisms it creates may pose direct, but unpredictable, health hazards Such concerns led a group of American biologists, headed by Paul Berg of Stanford University, to issue a call last July for a world wide suspension of research involving the technique, until the possible hazards associated with it have been evaluated (*Nature*, **250**, 175, 1974) This conference was called to try to assess the hazards and to decide under what circumstances such research should be resumed

The meeting concluded, in short, that some genetic manipulation experiments could go ahead immediately, provided fairly strict safety precautions are adopted, but that others should not be attempted until safer procedures have been developed It was also agreed that there are some types of experiments which are potentially so hazardous that they should not be carried out under any circumstances A statement of the principal conclusions reached at the meeting is now being drawn up

It was remarkable that even a statement of general principles was approve by all but a tiny handful of participants at the conference, for at times it seemed inevitable that there would be a disastrous split between those who

Berg conference favours use of weak strains

from Colin Norman, Pacific Grove

wanted to press ahead with their experiments and those who were arguing for restraint In the end, however, the rift was healed by the realisation that safer procedures could be developed very rapidly to allow virtually all the planned experiments to proceed, so that any continuation of the suspension of experiments would be short lived The nub of the matter is that gene transfer experiments could be carried out much more safely using biologically disabled microorganisms which would be unable to survive outside the laboratory, instead of the organisms that are commonly used in genetic research Fortunately, it was generally agreed that by using what one participant described as "old fashioned steam genetic engineering", such enfeebled strains could be developed and produced in quantity in a matter of weeks, so that even the most gung-ho researchers were able to accept that it would be prudent to delay some of their riskier experiments until safer organisms are available

Coming as they do from the people who will be most affected by them, the proposed controls on such experiments may seem like the classic case of the fox being set to guard the chickens—in fact, they have already been criticised as such by a group of radical scientists known as Science for the People But the recommendations are much stricter than might be expected and, if implemented, they would require expensive modifications to many laboratories hoping to conduct gene transfer experiments They are also more stringent than recommendations published last month by a committee of British scientists, chaired by Lord Ashby, which concluded that although development of safer strains of experimental organisms would be desirable, present safety precautions would probably be sufficient to allow most experiments to proceed

The technique in question, according to Sydney Brenner of the MRC Laboratory for Molecular Biology, Cambridge, "is going to generate the most

exciting period, I think, in biology, and it is going to last for at least 10 years, maybe more" It involves use of a newly discovered class of enzymes, called restriction enzymes, to snip fragments of genetic material (DNA) from one organism and splice them to the DNA of another organism, such as a virus or bacterium

The key to the technique is that some restriction enzymes sever one strand of the double-stranded DNA leaving what are known as 'sticky ends' Two DNA molecules cut by the same enzyme will have identical ends, which can be joined together and annealed into a single molecule Three types of experiment using this method of cutting and splicing together DNA fragments from different sources have either been carried out or are being contemplated The first involves insertion of 'foreign' DNA fragments into a package of DNA called a plasmid, which can replicate inside a bacterium independently of the bacterium's chromosomes A second type of experiment involves splicing fragments of foreign DNA into the DNA of viruses called bacteriophages, which attack and replicate in bacteria And a third possibility involves joining together pieces of DNA from two different viruses, to form a hybrid virus

The scientific promise of the technique is that it will allow fragments of DNA which are believed to be responsible for initiating specific chemical reactions to be inserted into a bacterium and copied every time the bacterium divides The bacterial culture would then produce large quantities of the foreign DNA fragment, which could be studied more easily The technique also offers the possibility of taking particular genes out of their normal environment and studying how they operate in the simple genetic system of a bacterium And the construction of hybrid viruses may help to shed light on why some viruses cause tumours in animals

In addition to that potentially rich scientific harvest from such genetic manipulation experiments, the technique may offer the more remote possibility of isolating genes which code for nitrogen fixation in leguminous plants and introducing them into the cells of crops such as cereals If that could be accomplished the resulting hybrid cereals would no longer need a constant supply of nitrogen fertiliser Another widely touted possibility is

that it may be possible to mass-produce the genes responsible for promoting the synthesis of insulin by growing them in bacterial cultures

But the technique also involves the possibility of significant health hazards The essence of the matter is that by combining fragments of DNA from different sources an infectious organism might be produced endowed with unpredictable biological properties By splicing genes from two viruses, for example, the host range of the virus might be extended, so that a virus which does not normally infect might inadvertently be made to do so The consequences of transferring segments of DNA from animal tumour viruses to viruses which commonly infect man, for example, could be disastrous The chief reason for concern with such experiments is that segments sliced from a molecule of DNA by a restriction enzyme contain considerable amounts of genetic material in addition to the particular gene which is being studied, and the effect of that unknown DNA cannot be predicted in advance

Another cause for concern is that the bacterium most commonly used in genetic research is a laboratory strain of *E coli*, a bacterium which is normally present in the human gut Although Dr E S Anderson, of the Enteric Reference Laboratory, Colin Dale, presented evidence suggesting that the particular strain of *E coli* used in laboratory research does not survive for long in the gut in competition with other strains, it was universally agreed that more reliable safety factors are needed

That realisation led to perhaps the most productive session at the conference—a session during which specific mutations were discussed which could be built into laboratory viruses and bacteria used for genetic research, to ensure that the organisms would be incapable of surviving outside the medium in which they were cultured

According to Waclaw Szybalski, of the University of Wisconsin, such biologically enfeebled strains could be produced "by the time we have slept off this meeting " In short, the mutations would involve making bacteriophage lambda (the most commonly used bacteriophage for genetic manipulation experiments) unable to survive at human body temperature, unable to grow the tails needed to make it infectious, and able to infect only the particular modified strain of bacteria used in the experiment *E coli* could also be equipped with genetic mutations which would make it unable to synthsise diaminopimelic acid (DAP), a constituent of cell walls, so that it would have to be provided with DAP in order to survive. *E coli* could also be made temperature-sensitive

With the promise that such disabled organisms could be produced and made widely available in a matter of weeks, much of the concern about delaying experiments, which had been voiced during the first two days of the meeting, was considerably diminished Consequently, a draft statement, drawn up by the oragnising committee and discussed on the final day, was accepted by an overwhelming majority of the participants, even thought it called for many important experiments to be put off until safer laboratory strains of bacteriophage and *E coli* are developed

The draft statement outlined three levels of safety precautions which should be accompanying various genetic manipulation experiments Only the lowest risk experiments should be carried out with existing strains of bacteriophage lambda and *E coli*, the statement suggested, but they would require safeguards such as autoclaving all cultures, safe pipetting procedures and so on Such experiments would consist of gene transfers between organisms which normally exchange genetic material—in other words, no novel genetic combinations would result from the experiment—and the insertion of genes from invertebrates and cold-blooded vertebrates into bacteria

The next level of experiment—those embodying moderate risk—would require use of biological safety cabinets, negative pressure in limited access laboratories and use of some protective clothing Estimates of how much it would cost to equip a laboratory to conduct such experiments varied widely, but it was generally reckoned that at least \$20,000–40,000 would be needed In addition because physical safeguards cannot guarantee absolute protection against the spread of biological agents, such experiments should await the development of enfeebled strains of viruses and bacteria, the statement suggested Experiments such as the splicing together of DNA from viruses, linkage of viral DNA to bacterial plasmids, and the joining of fragments of DNA from warm-blooded animals to bacterial DNA would fall into this category

The highest risk experiments which could be done would again require the use of enfeebled strains of bacteria, and they should only be conducted in special laboratories equipped with airlocks to isolate them from other areas Protective clothing should be worn, and showers would be required on entering and leaving the laboratory Examples of such experiments are the fusion of genes to bacterial DNA when the resulting organism is likely to produce an agent toxic to the host, and work on viruses such as smallpox, which present a high risk in themselves

Finally, after much debate, it was agreed that there are some types of experiments which should be ruled out altogether Although such experiments were not defined, they would include the insertion into *E coli* of the gene which specifies production of botulinus toxin There would, however, be little justification for carrying out such experiments, except to produce lethal agents for biological warfare

A statement setting out those general principles was agreed to by all but about three or four participants Among the dissenters were two Nobel prizewinners, Joshua Lederberg, of Stanford University, and James Watson, of Cold Spring Harbor, both of whom had consistently challenged some of the basic assumptions underlying the conference

Lederberg, for example, said in a statement he distributed at the conference, that "research on recombinant DNA is, in my opinion, the central way in which molecular genetics can contribute to the solution of important medical problems" and he warned repeatedly that any delays in carrying out the research should take into account the fact that important benefits may also be delayed He also suggested that regulations governing such research are likely to be frozen in place, so that it would be difficult to make them less stringent later if it turns out that the risks have been overestimated Lederberg also took exception to the classification of experiments into only three classes, pointing out that most of the contemplated studies would fall into the low or moderate risk categories, but the difference between the two is "considerable reconstruction of a laboratory"

Watson drew attention to the discrepancy between regulations being proposed for genetic manipulation studies and those governing work on tumour viruses "As someone in charge of a tumour laboratory", he said, "we are working with something I feel is instinctively more dangerous than anything I have heard here", yet the regulations governing research on tumour viruses are relatively lax "I think you should just use common sense", he said, but added that "you will have to live with the fact that somebody may sue you for \$1 million if you are careless"

Underlying much of the discussion of the need for self-imposed controls was acceptance of the fact that science has lost much of the public support that it once enjoyed, and that if regulations were not imposed from within, legislation could be anticipated which would probably turn out to be much more restrictive Whether this unprecedented attempt at self regulation will work, however, remains to be seen □

Facing Israel's water problems

from Kapai Pines, Jerusalem

IN spite of a 25-year-old development scheme for water resources, Israel is faced with a crisis which threatens to damage seriously the country's agricultural programme The Israelis' ingenuity in water management has achieved spectacular results, particularly in the cultivation of the so-called wilderness areas, but now the country has reached the point where exploitable resources are strictly limited, while consumption is growing and promises to go on growing

Israel has a uniquely uniform pressurised supply system which encompasses virtually the whole country and integrates almost all of its water resources, 95% of available natural sources are used The problem is how to expand, and even to conduct, the system in a situation of growing demand and limited supply, exacerbated by the problem of deteriorating quality

Recently, water problems have been the subject of a lively public debate, in which almost everybody is trying to participate In a memorandum submitted to the Prime Minister, Mr Rabin, the Minister of Agriculture, Mr Ozan, appeals for an urgent allotment of IL 500 million for the development of new water resources this year Mr Ozan claims that there has not been any development of such new resources for many years and that, if immediate steps are not taken it will be necessary to divert 300 million cubic metres of water from agriculture in order to meet the expanding demands of urban consumption As a result, agricultural production will shrink by 25%

Further, on February 10, almost all the Knesset (Israeli Parliament) factions united in adopting a resolution calling for water planning funds to develop new water resources while carefully utilising the existing resources to the peak of their economy and efficiency The resolution warns against pollution of underground water, Lake Kinneret (Sea of Galilee), rivers and wadies, it calls for the implementation of sea water desalination by nuclear energy

It is characteristic that the experts are divided among themselves as to the right solution In the face of almost fully utilised natural resources what are the alternatives? There are several There is, of course, the possibility of limiting the growth of consumption and adjusting it to the level of supply It is also possible, some experts claim, to increase the actual yield of the resources by using water which has not been used for various reasons so far (brackish water or sewage effluents, very deep borehole well water or flood waters in winter streams) It is also possible to produce 'artificial water' (artificial rainfall and converted saline water) An additional way is 'mining' of water from underground reservoirs, which are one-time-only reserves

As far as desalination goes, almost all experts agree that the technologies available at present are generally too costly for producing water for agricultural use Since the urban and the industrial sections have been given priority, agriculture must take the blow □

Water yield and consumption in Israel (in millions of cubic metres per annum)

(a) Water yield

Resource	Potable water Present yield capacity (1972–73)	Potable water Estimated future development (end of century)	Marginal water (brackish flood water reclamation of waters, sewage effluents) Present yield capacity	Marginal water (brackish flood water reclamation of waters, sewage effluents) Estimated future development
Lake Kinneret (Sea of Galilee)	560	150		10
Main aquifers	960	20	160	20
Floods	30	20–40	13	8
Sewage Effluents		100	26	100
Desalination	2	12		
Total	1,552	302–322	199	138

(b) Water consumption

Sector	Potable water Consumption in 1972–73	Potable water Recent annual increase	Other waters brackish, flood-water, sewage effluents
Agricultural	1,175	20	167
Domestic	285	12	
Industrial	60	5	32
Total	1,520	37	199

Mr. Wilson's deal with Russia

from Vera Rich

THE recent visit of Mr Wilson to the USSR has resulted, *inter alia*, in an impressive programme for scientific and technological cooperation between the UK and the USSR for the next decade This programme is, in fact, a conseqeunce of a number of meetings and discussions on this theme, going back as far as 1968 and culminating in the Agreement on the Development of Economic, Scientific, Technological and Industrial Cooperation signed in London on May 6, 1974

The programme envisages a wide range of activities in which scientific and technological cooperation can be "encouraged" on a "mutually advantageous basis", ranging from high temperature plasma physics to "continuous beer production", and it is difficult to assess how far any particular clause will be implemented Some subjects seem to have been included on a rather unilateral basis—it is difficult to to see, for example, what precise benefit the UK would receive from the joint study of irrigation—and others are already there as a sop to the prevailing trends of world opinion (energy-saving studies and reduction of diesel exhausts), yet others (such as astronomy) are so wide ranging that it is difficult to know precisely what cooperation is envisaged To complicate the matter further, the official programme blandly states after an impressive list of fields of cooperation that it is only "of a recommendatory nature, and is subect to modification and adjustment as and when necessary", a statement which appears to be something of an escape clause

Nevertheless, some areas of cooperation can be defined more closely A general statement of cooperation on "flameproof equipment for use in mines subject to sudden gas emissions and coal and rock bursts" seems to link up with a clause in the detailed schedule on "Cooperation to equip Soviet mining machines supplied to the United Kingdom with British-made electric equipment in accordance with British safety standards" (a somewhat surprising statement in view of the frequent *Novosti* releases on the safety of the Soviet mining industries) and the suggestion that the Soviet Union should participate "in the realisation of the programme of the National Coal Board for the modernisation and expansion of coal output" (which could raise some piquant problems with the Trade Unions) Meanwhile, in the Soviet Union, British know-how is to be used in the supply of goods ranging from "airport equipment" to "equipment for

THE Indian University Grants Commission (UGC) has decided that emphasis during the Fifth Plan will be on consolidation and strengthening of existing university departments Because of severe financial constraints, the UGC has asked all universities to curtail expenditure and limit their programmes according to its guidelines Accordingly, the universities have been asked to formulate detailed programmes for development of existing teaching and research departments, introduction of new areas of specialisation in existing departments and setting up of individual departments, measures such as updating and modernisation of courses, and giving specific orientation to research activities, improvements in library facilities and services and general amenities for students and staff, such as study centres, hostels, residential quarters and health centres The universities have also been asked to see that, while they plan new programmes, those initiated during earlier Plan periods are properly implemented

At the undergraduate level, the UGC proposes to allow little or no further expansion in enrolment during the Fifth Plan, at least for formal, full-time studies Expansion, if any, will come about only through part-time evening classes or correspondence courses It has also been decided that the affiliated colleges would receive UGC assistance during the Plan, primarily for strengthening their faculty, improving their library and laboratory facilities, and installing workshops and related facilities The colleges have also been advised to give priority to re-orienting their courses so that they become relevant to local, regional and national needs and emphasise utilisation of available natural resources

● The UGC report for 1972-73, analysing the emerging problems and perspectives of higher education in India, blames unrest among students on the present system of examination, obsolescence of university curricula and the lack of good social life in colleges and universities

The report points out that enrolment in university-level courses has left growth rate of the national economy way behind, resulting in lower per capita investment in higher education and also deterioration in standards of institutions where facilities are being stretched to breaking point in accommodating increased student populations (In 1972-73, there were 35 44 lakh students enroled in 4,153 colleges in the country)

Referring to growing unemployment among the educated, especially women and those who graduate from the universities in sciences and various professional courses, the report says that

Educating India

from Narender K Sehgal, Jullundur

much undergraduate education is not relevant either to the abilities and aptitudes of students or to the needs of the nation With a very high failure rate at first degree level (about 50%) and large proportions of students being placed in the "third division" (aggregating less than 50% in an examination) at the postgraduate level, the report feels that "the present system of higher education is generating much waste and stagnation" and that "this raises serious doubts about the well being of the university in India "

The report further points out that the spread of higher education has not been very even, both area-wise and population-wise N e i t h e r backward areas, nor students from these regions, have been able to get their fair share of facilities or opportunities for higher education — meaning that disparities have grown worse

The commission blames on paucity of funds its inability to play a role in developing a system of higher education best suited to the genius of the people and the development of the country It proposes a dialogue with the universities with a view to determining what can be done during the period of the Fifth Plan to make higher education a "little more meaningful and ultimately a fit instrument of change and development "

● The University Grants Commission has proposed 'radical' reforms in the present examination system Meerut University, in Uttar Pradesh, is likely to be the first to try out the reform on an experimental basis during the next academic year Similar experiments are also expected to be launched in universities in other states

Central to the proposed reforms is what is called a 'question bank' Such a bank will have up to 100 questions which will be published and made available to both students and teachers at the beginning of the academic term Seventy-five per cent of the questions asked in an examination will be taken out of the bank and the rest (25%), mostly numerical problems, from outside The curriculum and the question bank for each course of study will be framed by Boards of Studies to be constituted for the purpose

Also proposed is a card system for the examination questions The cards containing questions, to be answered by individual examinees, will be picked up using a random process from a collection (This will hopefully help reduce the use of unfair means at examinations—a very prevalent feature at present) The candidates will be able to appeal to a committee if, on receiving the evaluated answer books, they feel dissatisfied with the evaluation The committee will consist of the college principal, the teacher for the course and a representative of the students

A university will be free to cancel a student's admission if he/she gets a 'D' grade in all his/her examinations and assessments The grades A, B, C and D will replace the 'marks' being awarded in evaluations at present

Universities as well as colleges will be required to conduct sessional or continuous assessments of students which will be shown on their grade sheets separately, as this will be aimed at measuring their "essential abilities" The name of colleges will also be mentioned on the degree/diploma of a qualifying student The performance assessment of students will be required to be made over well distributed intervals of time

Meanwhile the Union Education Minister recently told a meeting of the consultative committee attached to his ministry that the present examination system had collapsed completely and that reforms in this direction were urgently needed He informed the members that 11 out of the 12 universities selected for launching examination reforms suggested by the UGC had already set up special implementation committees for the purpose ☐

---

the production ot tufted carpets"

Cooperation in the field of raw materials likewise ranges from window glass and timber products to "the enrichment of uranium in the Soviet Union from the raw material of British customers '

In general, the technological section of the programme tends to become bogged down in detail, and the order of the items would surely form a fascinating study for the psychologist (cars, for example being listed immediately before toys) There is, however, a general overall stress on computer hardware and software, power production, including atomic power stations, heavy ridge group of exposed sediments ☐

Wrong skull

THE skull illustrated on page 578 (February 20) was in fact KNM-ER1470 found at East Rudolf in 1972 It has been assigned to the genus *Homo,* sp indet , and was found during prospecting in area 131 on the Karari industry and means of transport ● ☐

SCIENCE and technology are receiving a new emphasis in the Arab world, partly as a result of the increased wealth of the oil-rich countries The new source of wealth has made possible educational and research facilities, new institutions and programmes hitherto out of reach for most of the countries in the area The first Conference of Ministers of Science and Heads of National Science Policy Organisations of the Arab States was held in Baghdad last year, and an Arab League Educational, Cultural and Scientific Organisation (ALESCO) has been formed in recent years to promote Arab culture, including science and technology A number of Arab states have formed—or are forming—science policy machinery and programmes, emphasising applied research

Egypt has traditionally been the most advanced Arab nation in science, and has built up a large pool of professionals who are much in demand in other Arab states Iraq, which today has an ambitious five-year science plan, takes a distant second place But while Egypt is poor, Iraq is now rich, and any promising research project can obtain funds there Yet, ironically, Iraq is poor in personnel

Trained personnel, in fact, are the main need of the Arab countries generally Countries relatively rich in scientific manpower—Egypt, Lebanon and Jordan—are supplying the rest with personnel Countries like Kuwait and Saudi Arabia are busy building laboratories and universities and advertising openings for staff

Because of the wide differences in resources between the Arab states, Dr Ibrahim R Shimi, head of the chemistry department in Ain-Shams University, Cairo, has proposed that a research council be established in the League of Arab States to which member states should allocate a proportion of their GNPs This council would set up specialised research centres dealing with problems common to the area as a whole, such as cultivation of arid lands and desalination of sea water

The Arab countries' experience with science policy formulation is varied Egypt's has been complex, and began with its Science Council, established in 1956 The Science Council produced a national research plan for the universities, the new National Research Centre laboratories and the specialised institutions belonging to the ministries

This council was superseded in 1961 by the Ministry of Scientific Research In 1965, the Supreme Council of Scientific Research came into existence —but it was short lived and was replaced by the Ministry of Scientific Research in 1968 The Ministry in turn was replaced in 1971 by the Academy

of Scientific Research and Technology The president of the academy, at present, Dr A Abou-El-Axm, has ministerial rank and is responsible to the Prime Minister

The academy not only formulates science policy but supports research and technology through grants It also coordinates major projects, participates in development of science curricula, supports scientific conferences, and organises scientific publications and the popularisation of science, among other things In addition, it is responsible for a number of research institutions in such areas as atomic energy, oceanography, petroleum and metallurgical research, and research on bilharzia

The Arab World science revival

from David Spurgeon

Grain sorghum research, Lebanon

By comparison, Lebanon's history of science policy has been uncomplicated It began in 1962 with the establishment of the National Council for Scientific Research (NCSR), and this single body not only was the first science policy-making body, but has continued as the sole one The situation is further simplified by the fact that the same body that formulates policy also sees that it is carried out

Lebanon went about its science policy planning deliberately and directly The underlying assumption was as stated in its Five-Year-Plan for the Organisation and Development of Scientific Research in Lebanon

"Lebanon is a small country with limited human and material resources Its aspirations, whether for a higher standard of living or an enhanced cultural standing, can therefore only be conceived and implemented through utilisation of its resources, human and material at the maximum possible

efficiency"

The NCSR therefore went about setting up the national science plan by first asking the Ministry of Planning what the country's overall objectives were It promptly received a reply listing maximum regular increase of the national income, equitable distribution of the national income among citizens, full employment, establishment of an equilibrium among the various economic sectors, and rational distribution of the population over the territory of Lebanon

Eighty per cent of the plan deals with oriented research according to priorities carefully and simply laid out, 20 per cent deals with non-oriented or basic research Themes accorded top priority are Lebanese climate, conservation of the natural milieu, health and disease in Lebanon, housing, and what are called "the essentials of productivity"— Lebanese raw materials, soil and water, and marine resources NCSR's 1973 budget was 5,250,000 Lebanese pounds

Some examples of the projects funded by the NCSR illustrate the strongly practical philosophy behind the plan development of a high-protein, vitamin and mineral biscuit for low income groups, the study of Lebanese plants used in folk medicine with the aim of isolating and analysing their active elements with a view to their exploitation or synthesis, the industrial production of fish and molluscs using recycled human wastes, and research on processing of surplus fruit crops

Joseph Naffah, Secretary-General of the NCSR, says that the practical orientation was adopted partly to attract attention to the accomplishments of science and to improve the climate of research, because in Lebanon, "the scientist is not respected in the sense that the self-made man is respected"

There is also a surprising amount of attention being paid to the popularisation of science Salah Gelal, science editor of Cairo's newspaper *Al Ahram*, heads a staff of 12 science reporters and, with the financial backing of his newspaper, organises science clubs and fairs for Arabic youth Last year, in Baghdad, UNESCO and the Union of Arab Broadcasters sponsored a meeting on the popularisation of science, and training symposia have been held and attended by representatives of a number of Arab countries In fact there seems to be a growing realisation that the real costs of the area's long involvement in war include not only lost lives and material waste, but also a retardation of national development The Arab states see a revival of science as essential to the fulfilment of their nation's potential ☐

correspondence

Visa problems

SIR,—In your issue of December 13, Miss Peller gave an account of her experiences in trying to attend the Ninth FEBS Meeting in Budapest last August As Chairman and Secretary-General, respectively, of the Federation of European Biochemical Societies at that time, we naturally regret that Miss Peller was unable to obtain a Hungarian visa in time, although we have been assured by the organisers of the meeting that a visa was in fact available, unknown to her, in Vienna three days before the meeting started

Because there are no diplomatic relations between Hungary and Israel it was anticipated that it would be difficult for biochemists in Israel to apply for Hungarian visas This problem was discussed during a visit to Budapest in February 1974 by the then Secretary-General of FEBS and Professor S G Van den Bergh, the FEBS meetings adviser In consultation with the organisers of the FEBS meeting (the Hungarian Biochemical Society and the Hungarian National Academy of Sciences) a special procedure was worked out which enabled Israeli biochemists to send their passports some months before the meeting by diplomatic mail to London, where the FEBS Secretary-General obtained Hungarian visas on their behalf within 24 hours and then returned the passports and visas to the applicants in Israel, again by diplomatic mail Though somewhat elaborate, these arrangements worked satisfactorily in the case of applications received in good time through the Israeli Biochemical Society They did not, however, cater for biochemists like Miss Peller, who were not resident in Israel at the time and therefore applied directly to Hungarian consulates

In Miss Peller's case there is at present a fundamental discrepancy between the information she received at the Hungarian consulate in Vienna where she was told she was on a "black list" and would not be admitted into Hungary and telegrams she received by one of us (H R V A) from the meeting organisers some days before the meeting started stating that her visa had been granted Although we have not yet been able to resolve these apparent contradictions, we believe that a genuine effort was made both by the organisers of the FEBS meeting and the authorities in Hungary to establish a satisfactory procedure for dealing with all visa applications and there is no evidence to suggest discrimination in the issue of visas

Nevertheless, we think that there are several important lessons to be learnt by the organisers of future international conferences, as well as by intending participants Principally, there is a need to ascertain at an early stage of planning a meeting the precise official regulations of the host country concerning visa applications, to include this information in the circulars sent to all intending participants, to make and publicise special arrangements for citizens of countries which do not have normal diplomatic relations with the host country, and to urge participants to apply early for visas Finally, we believe it would be useful, particularly in the case of large conferences, to appoint a member of the organising committee to be responsible for dealing with urgent visa problems and to announce his name, address and telephone number well in advance of the meeting so that contact can be made quickly if and when participants have special difficulties

Yours faithfully,
L L M van Deenen

H R V Arnstein
King's College, London

SIR,—In continuation and support of S Peller's letter (December 13) I would like to point out that I was, obviously on the same grounds, subjected to an identical procedure by the diplomatic authorities of the host land of the Extraordinary General Assembly of the International Astronomical Union at Torun in September 1973—in spite of possessing an official invitation

Although I was far from active politically or in any other way that could interfere with the interests of the host country, and despite rigorous adherence to the instructions printed on the invitation, I was refused an entry visa and thus prevented from attending the assembly I wish to thank all colleagues who tried—in vain—to change the decision at the very last moment

Yours faithfully,
Andrei R Serban
Heidelberg

IQ Statistics

SIR,—A recent editorial (September 27) has drawn attention to the unfortunate social consequences of the recent controversy about the possibility of genetic contributions to the observed differences between the average IQs of different races It does not seem to have been noticed that many of the contributors to the debate, on whatever side, have quite misunderstood the logic of the relevant statistical methods

If, as a first approximation, we assume that the observed IQ of an individual is the sum of a genetic component, G, and an environmental component E, so that $I=G+E$, it has become customary to define a 'coefficient of heritability', h^2, as the ratio of the variance of G to that of I In doing this the tacit assumption is made that G and E are uncorrelated in the population so that the variance of I is the sum of the variances of G and E This is usually the case for quantitative characters in animals and plants For human IQ, however, there is no doubt whatever that G and E are correlated, environment (both physical and psychological) being strongly associated with intelligence Thus there is no point in attempting to estimate h^2 since it cannot be defined, let alone estimated, and attempts to estimate in are a misapplication of the analysis of variance

It is of course, true that it might be possible in theory (but very difficult in practice) to divide the variance of I into three terms, the variances of G and E, and their covariance, and even to go further and split the variance of G into linear, dominance and epistatic components

Even if this could be done, however it is clear that such components of variance within a population throw hardly any light on the differences between populations This is easy to illustrate on animal and plant populations where h^2 within populations, when it can be defined, has no relationship to population differences

At present there exist no methods of estimating differences in mean levels of G, and there is no evidence of any kind which suggests that negro intelligence is on the average, less than, equal to or greater than that of white people These three hypotheses are not intrinsically unplausible but those who think they can be tested empirically have been inadequately instructed in the analysis of variance by their statistical colleagues

University competition

SIR,—J B S Price's lament about unfair competition from university-inspired science-based companies cannot be allowed to go unanswered

One has sympathy for a company like Mr Price's which attempts to make profit from difficult technology—too often the development costs are unlikely to be justified by the potential market Science often requires such development to advance a subject, however, and without it no market could possibly develop It is just such devices that are likely to be spawned by university staff The important question for the scientific instrument industry in the UK is How do we get such schemes financed? Certainly not from companies like Mr Price's, in 1975 And only partially from the NRDC—50% on very hard terms

I am surprised he fears university competition on hardware No university can operate such activities except on a very small scale and has no sales organisation If the scale is small, it is unlikely to be profitable for such companies as Grubb Parsons in any event and perhaps should be tackled by a smaller company

He has less to fear than he thinks, such operations are rarely very professional and most buyers won't trust universities to come up with the goods —again keeping the scale small There are, of course, university entrepreneurs who expand their activities rapidly, becoming fully commercial and professional They then, however, face all the problems of production facilities, cash-flow and overheads that Mr Price does Their sole advantage is their enterprise and enthusiasm

I write because a negative attitude to this problem will only lead to featherbedding, with enough of that, the competitiveness of British scientific industry will continue to diminish to the disadvantage of our balance of payments

Whatever is said, we must find an effective way to turn the country's considerable investment in university research into industrial progress

Yours faithfully,
S D SMITH
Heriot-Watt University

Taboo research?

SIR,—Some 20 years ago the first infectious virus was reconstituted in the laboratory from component chemicals, and some religious circles, Catholic as well as fundamentalist, were wondering whether to disapprove such research activities on the grounds that they were approaching too close to God's territory They wisely and fortunately remained silent

This week an international group of scientists and science administrators

met at a resort on the coast of California to discuss the merits, or rather dangers, of a much more advanced research on similar lines which is going on all over the world I hope that this group will show as much wisdom as the churches did earlier Taboos to block, or guidelines to channel man's curiosity have never succeeded in the long run, and usually they appeared ridiculous a few decades later They are as old as the caveman's wife telling her mate not to bring that burning piece of wood from the tree hit by lightning into the cave, and not to pick up that club-shaped branch when attacked by a bear Yes, there was danger in these activities—man could and did hurt himself as a consequence of each of these acts The end effect of these activities, however, is that *homo sapiens* has greatly multiplied and that ever more members of the species live longer, more healthily and more comfortably than before

Another result is that people are now able to arrange world-wide meetings, with busy scientists travelling through the air, very rapidly and rather safely, to discuss further steps in unknown directions, and their dangers, and guidelines to hamper these steps Man also developed remarkable means of communication so that the original fears and misgivings of the caveman's mate ('caveperson', so as not to prejudge who brought the fire in) are now brought to everybody's attention and the weak, timid, conservative (not to say conservationist) members of the species may through their numbers be able to exert real pressure on the Promethean creative curious individuals, to make them cease and desist The human species as a whole has, however, survived, and benefited, from the discovery and utilisation of fire, the wheel, powder, the steam engine, vaccination, electricity, dynamite, fluoridation and atomic energy It will surely hardly notice that some scientists are suffering from extrapolatotis and super-scrupulosis Thus the danger of the present meeting to future research is surely small, if any, and of short duration The fact that this is a court of scientists sitting in judgment on scientific research makes it more disturbing and regrettable, however, in that it shows to what extent the anti-intellectual disease of doubting the value of progress and advance of knowledge has spread to the ranks of the presumed Prometheans

H FRAENKEL-CONRAT
University of California

Naming names

SIR,—I would like to align myself with those anthropologists, such as Robin A Drews, who have a proprietary attitude

toward the proper spelling of Peking man (Peking, please, not Pekin) My own proprietary attitude extends to the Peking duck (*Anas platyrhynchos*) Although it is probably too late to do anything about Pekin, Illinois, USA, I do hope we can rescue the " big, white duck known as a Pekin variety" from nomenclatural ignominy

First of all, there is no Pekin, China The name Peking comes from two Chinese characters, the first of which (pei) means northern and the second of which (ching or king) means capital Although some anthropologists suspect 'Americanism at work' in the base misspelling of their favourite fossil remains and my favourite domestic waterfowl, I have developed a different hypothesis in the course of years of grappling with this persistent problem in orthography

The Peking duck originated in China and was first noted in the USA around 1870, but I can't determine from whence it came I had always assumed Europe While reading some marginalia in Jean Delacour's engaging volumes on waterfowl systematics, I observed that he claimed to have visited Pékin, China in the course of his studies I was a little dismayed that such an obviously literate and well travelled scientist could be found among the ranks of orthographic incompetents until I learned that in the French language Peking (whether city, duck, or man) is Pékin Thus, I arrived at an essentially francophilian explanation of the entire business, to wit, the forlornly foreshortened Pekin represents the uncritical (and incomplete) adoption of the French word for Peking *Voilà!*

GILBERT GOTTLEIB
Raleigh, North Carolina 27611

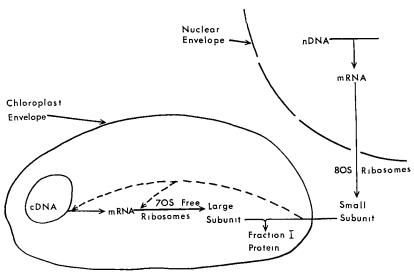
SIR,—The term 'exobiology' excludes life on Earth It is, of course, impossible at present to study exobiology without reference to life on Earth Even if several extraterrestrial life forms were discovered tomorrow, nobody would study them without comparing them with terrestrial life Thus there is a need for a word which includes all life forms in the universe

The term cosmochemistry is already well established and has been defined as 'the branch of science which treats the chemical composition of the universe and its origin and evaluation" It would thus seem to be appropriate to use the term cosmobiology for the study of life in the Universe I believe that such matters of terminology are not trivial, for the manner in which a science is divided into branches has a significant effect on the development of that science

Yours faithfully,
A A COTTEY
University of East Anglia

news and views

Chloroplast protein synthesis

from Harry Smith


READERS of the more distinguished biochemistry and molecular biology journals could be forgiven for concluding that plants do not have genes, nucleic acids, proteins, enzymes and intriguing regulatory processes such as are possessed by respectable organisms like *E coli* and HeLa The omissions are doubtless due to the small amount of work in progress in these areas of plant science, which is, in turn, largely caused by lack of interest in, and knowledge of, plants on the part of traditionally trained biochemists It is, therefore, refreshing to see a group tackling one of the central problems of plant molecular biology and in the process producing a concept of interorganelle regulation which may have important implications for other organisms

R J Ellis and his colleagues at the University of Warwick have for several years now been studying the complex problem of the synthesis of Fraction 1 protein in leaves This protein, which may represent up to 50% of the total soluble leaf protein, is only found in its intact state within the chloroplasts, where it carries the catalytic function of ribulose-1,5-diphosphate carboxylase, the enzyme responsible for photosynthetic carbon fixation The molecule has a molecular weight of about 525,000 and probably consists of eight identical large subunits (molecular weight about 55,000) and eight to ten identical small subunits (molecular weight about 15,000) Genetic experi-

ments have shown that the functional gene for the large subunit is present in the chloroplast genome, whereas that for the small subunit is in the nuclear genome Moreover, earlier inhibitor experiments indicated that the large subunit is synthesised only on chloroplast ribosomes *in vivo*, and the small subunit on cytoplasmic ribosomes There is thus a fascinating problem of interorganelle communication and integration.

In 1973 Blair and Ellis (*Biochim Biophys Acta*, **319**, 223–234) showed that intact, isolated pea chloroplasts when driven by light energy, incorporated labelled amino acids into the large subunit of Fraction 1, the only soluble polypeptide to be synthesised Its identity was established by comparing a tryptic map of the labelled peptides with that from authentic Fraction 1 large subunit Subsequently, Eaglesham and Ellis (*Biochim Biophys Acta,* **335**, 396–407, 1974) showed that isolated chloroplasts in the light incorporate label into six separate membrane-bound products which were considered to be membrane proteins Other workers have obtained similar results using spinach chloroplasts, but in this case upwards of four soluble proteins, and nine membrane proteins, became labelled (Bottomley, Spencer and Whitfield, *Archs Biochem Biophys ,* **164**, 106–117, 1974) The concept has thus developed that at least Fraction 1 protein large subunit and a

number of chloroplast membrane proteins are synthesised on chloroplast ribosomes The location of the genes for the membrane proteins is not yet known

Hartley, Wheeler and Ellis have now demonstrated (*J molec Biol ,* **91**, 67–77, 1975) the existence of the messenger RNA for the large subunit by the only real criterion—its *in vitro* translation into a recognisable polypeptide Using a cell-free *E coli* preparation as a heterologous protein-synthesising system, they showed that the Fraction 1 large subunit is synthesised when total spinach chloroplast RNA is presented as the message Two major labelled products were found, both in the cell-free heterologous system, and as a result of protein synthesis by intact light-driven chloroplasts One of these, with a molecular weight on SDS gels of 52,000, had a closely similar chymotryptic map to that of authentic Fraction 1 large subunit The evidence for the identity of the labelled product with Fraction 1 large subunit seems most convincing

Since the large subunit is coded for in the chloroplast genome, its messenger RNA is present in chloroplast RNA, and it is synthesised on chloroplast ribosomes, some control of synthesis must be exerted such that the relative proportions of large and small subunits are coordinated In the January issue of *Phytochemistry* (**14**, 89–93, 1975) Ellis puts forward a very intriguing hypothesis for the mechanism of this integration He shows that MDMP (2(-4-methyl-2,6-dinitroanilino)-N-methylpropionamide), a highly specific inhibitor of initiation on 80S ribosomes, inhibits the synthesis of both the large and the small subunit when applied to intact pea leaves MDMP does not inhibit protein synthesis in chloroplasts On the basis of this evidence, a model is proposed in which the small subunit is thought of as a positive factor required for the initiation of either the transcription of the messenger RNA for the large subunit, or for its translocation (see figure) On this model, the synthesis of the large subunit by isolated chloroplasts represents run-off of preformed polyribosomes, which accounts for the observed rapid falling off in the rate of protein synthesis This elegant and painstaking work convincingly demonstrates that plant molecular biology is not dead, but is merely awaiting the attention of competent and dedicated biochemists

Cause and effects of global cooling

by John Gribbin

A RECENT flurry of papers has provided further evidence for the belief that the Earth is cooling There now seems little doubt that changes over the past few years are more than a minor statistical fluctuation

Last year, Kukla and Kukla (*Science,* **183,** 709, 1974) reported satellite observations of the sudden growth of ice cover in the northern hemisphere in the winter of 1971–72, and suggested that the increase was equivalent to one-sixth of the change needed to bring about a full ice age On page 45 of this issue of *Nature,* Wahl and Bryson compare recent sea surface temperature patterns with those of cooler regimes in the past, and conclude that over the period from 1951 to 1972 there was a decline corresponding "to a return of about one-sixth of the way to a full ice age" It is tempting to suggest that the change in sea surface temperatures contributed in some way to the spread of ice noted by Kukla and Kukla

But there is as yet no evidence that further cooling is likely in the immediate future The observed cooling corresponds to a re-establishment of the 'Little Ice Age' which persisted for several hundred years up to the end of the nineteenth century, it may be that all that has happened since 1950 is that the unusually mild spell of the first part of this century has ended Over the past millenium, icier conditions than those of today have been the norm Indeed, ice ages have been common over the past two million years But on longer time scales still, such cool phases are relatively rare events—and there is now a plausible model to explain why this should have been so

At present, the land surface of the Earth is concentrated in the northern hemisphere, around the almost land-locked polar sea This is a situation which can encourage the spread of ice much more than if warm water could easily penetrate to the polar sea, although of course polar ice forms even more easily when the pole is covered by land, as in Antarctica today It seems that over the past couple of million years this distribution of the continents has resulted in a fairly delicate balance between ice ages and inter-glacial regimes If ice cover is established, its high albedo is enough to maintain glacial conditions for a long time, but once the ice has gone a definite trigger (such as volcanic activity or changes in the Earth's orbit, see page 20) is needed to re-establish it

Calculations presented by Sellers and Meadows (on page 44 of this issue) support the commonly held view that the present-day distribution of northern continents may be the root cause of the wave of ice ages in the past two million years Neglecting other effects, if the continents were gathered in a belt around the equator, Sellers and Meadows find that the difference in albedo from conditions like those of the present would raise the global mean surface temperature by 12 °C

Much more work of this kind needs to be done before plate tectonics can provide a full insight into the long-term changes in patterns of glaciation, but at least the link between continental drift and ice ages is now beginning to be put on a quantitative basis

Eukaryotic operon

from P J Ford

GENETIC regulatory systems in prokaryotes are quite well understood compared with those in eukaryotes Regulator genes code for regulator substances (usually proteins in prokaryotes) which function by interacting with regulator sites (operators) in the DNA adjacent to the structural genes under control and with small molecules (either inducers which are usually substrates or repressors which are usually end products) which alter their affinity for the regulator sites A simple model supposes that regulator substances exist in two forms, one capable and one incapable of binding to the regulator site Inducers and repressors shift the equilibrium between these two forms

Four types of gene control circuit are theoretically possible using these components Negative control exists when the binding of regulator protein (repressor) at the regulator site inhibits gene transcription In this case gene activity may be restored (induced) by inactivation of the repressor in the presence of inducer or eliminated (repressed) by activation of the repressor protein in the presence of co-repressor substance which is essential for repressor activity Positive control exists when binding of regulator protein (inducer protein) at the regulator site is essential for gene transcription Inducible positive control is found when the presence of an effector substance (co-inducer), as well as inducer protein, is required for gene activity and repressible positive control occurs when the co-repressor inactivates the inducer protein, eliminating gene activity

Regulator gene mutants in negative control circuits must be recessive if structural gene function occurs in the absence of inducer (constitutive) or in the presence of co-repressor (de-repressed), or dominant if there is no expression in the presence of inducer (uninducible) or in the absence of repressor (super-repressed) In positive control circuits the dominance and recessive relationships are reversed Mutations in regulator sites are always dominant when linked (*cis* configuration) to structural genes and recessive when unlinked (*trans* configuration) Mutations in regulator sites of negative control circuits are constitutive or de-repressed and of positive control circuits are uninducible or super-repressed

These four theoretically possible types of simple control circuit are not equally used Most control circuits in prokaryotes are under negative control and either inducible, like the lactose operon, or repressible, like the tryptophan operon An inducible positive control system is the cyclic AMP system which controls several inducible operons (galactose for instance) and such operons are under dual control In this system cyclic AMP, which is neither a substrate for, nor a product of the enzyme pathway, activates a binding protein which is required for transcription of the operon A further complication may arise when a regulator protein acts both in a negative and a positive way such as is found in the control of the arabinose operon In this circuit the regulator protein acts as a repressor in the absence of arabinose but in its presence binds to an initiator site, allowing gene activity

A second type of control site (called promoter or polymerase binding site) which may be completely separate from or partially overlap the operator site has been found in many prokaryotic control circuits Promoter sites are usually located distal to negative and proximal to positive control operators Theoretically, positive control may be exercised by interaction of control proteins (sigma factors) with the polymerase core enzyme altering its specificity towards promoter sequences Mutations in promoter sequences will

US Department of the Interior

PART of North America's largest herd of caribou which migrates yearly between forest and tundra in northwestern Alaska. They regularly cross the basin of the Noatak river, one of the proposed National Wildlife Refuges which will be created as a result of the Alaska Native Claims Settlement Act of 1971.

The Noatak region lies in a transition zone between northern boreal forest and arctic tundra. With 500 species of vascular plants the flora of the proposed 7.5 million acre refuge is as great as that of the whole of Greenland or Iceland. The Department of the Interior intends to establish a 20-year moratorium on any developmental activities in the region to allow a comprehensive analysis of this intact slice of arctic ecosystem to be conducted. At a time when immense pressures are being applied to arctic ecosystems, in the form of roads, pipeline corridors and oil and gas extraction fields, the decision is as wise as it is opportune. What is learned from the analyses will benefit not only the future of the Noatak region but perhaps the future of all arctic lands.

be *cis*-dominant and *trans*-recessive and may be either 'up' (increasing transcription) or 'down' (decreasing transcription) in phenotype.

Clustering under common genetic control of the structural genes for enzymes of the same metabolic pathway is seen in prokaryotes but not eukaryotes, and represents an apparent distinction between these major phylogenetic groups. Taken together with their greater genomic complexity, the presence of large amounts of redundant DNA sequence and their intricate patterns of development and differentiation one might expect the gene control processes of eukaryotes to involve something more than those seen in prokaryotes. But the genetic analysis of gene control in eukaryotes has hardly begun and it is too early to say whether this expectation will be fulfilled. Two articles (Arst and MacDonald; page 26; Arst and Scazzochio, page 31) in this issue of *Nature* identify regulator sites involved in the control of two enzyme systems in the ascomycete fungus *Aspergillus nidulans*.

Proline catabolism in *Aspergillus* involves three enzyme activities: a permease, an oxidase and a dehydrogenase, which are under three distinct forms of control—induction by proline, nitrogen metabolite repression, and carbon catabolite repression. A probable structural gene for the permease (*prn*B) is tightly linked to a probable structural gene for a component common to both the oxidase and dehydrogenase (*prn*A). *prn*A⁻ mutants lack oxidase and dehydrogenase and *prn*B⁻ mutants lack the permease. All three activities are inducible, permease and oxidase are carbon catabolite repressible (dehydrogenase was not investigated), but only oxidase and dehydrogenase are nitrogen metabolite repressible—the permease is not. The two repression systems seem to act independently of each other. A gene *are*A is probably a regulator gene producing a positive control element which allows the synthesis of a large number of enzymes and permeases involved in nitrogen metabolism. One class of mutants (*are*Aʳ) leads to inability to use a variety of nitrogen sources including proline and presumably lacks a functional *are*A product. Second site mutations, called *prn*ᵈ, restore the ability of *are*Aʳ mutants to utilise proline as a nitrogen source. *prn*ᵈ mutations are *cis*-dominant, *trans*-recessive mapping betwen but not suppressing or allelic to *prn*A⁻ or *prn*B⁻ mutations, which are themselves tightly linked. *prn*ᵈ mutations do not significantly affect the induced levels of enzymes and are probably best interpreted as carbon catabolite derepressed since uninduced levels of the products of both *prn*B (which is not ammonium repressible) and *prn*A are higher in *prn*ᵈ mutants than in wild type in the presence of partial glucose repression.

The model favoured by Arst and MacDonald to explain their results of a regulator site (*prn*ᵈ) located between two structural genes (*prn*A and *prn*B) is reminiscent of the divergent arginine operon in *E. coli*. They suggest that *prn*ᵈ may be the binding site for a negative control element produced by a gene, such as *cre*A, identified by mutations which are commonly recessive and lead to carbon catabolite derepression.

In a second paper Arst and Scazzochio describe the isolation of a second site revertant (*uap*-100) of a mutant *are*-102 which has reduced levels of, among other enzymes, uric acid/xanthine permease. *uap*-100 is tightly linked to the probable structural gene (*uap*A) for uric acid permease. It is *cis*-dominant, *trans*-recessive and after maximal induction has a permease activity 2.5 times that of fully induced wild type. They interpret these results as identifying a regulator site with promoter-like properties.

Although the description of these two control systems is at an early stage it seems likely that Arst and his colleagues have identified an operon-type structure involved in proline catabolism and a promoter-like regulator site adjacent to the putative structural gene for uric acid permease in the eukaryote *Aspergillus nidulans*. The recent results of Hynes (*Nature*, **253**, 211; 1975) suggest that a similar regulatory mechanism affects the structural gene for acetamidase in *Aspergillus nidulans*.

Are mantle plumes jets or blobs?

from Peter J. Smith

IN a series of reports appearing over the past two years or so, Schilling and his colleagues (see, for example, Schilling, *Nature*, **242**, 565; 1973 and Hart *et al.*, *Nature phys. Sci.*, **246**, 104; 1973) have presented geochemical evidence which they claim is consistent with, and thus appears to support, the existence of a rising mantle plume beneath Iceland. In particular, they have interpreted the chemistry of basalt lavas from Iceland and surrounding areas in terms of two distinct magma sources—the conventional asthenosphere and a plume of hot primordial material derived from a much greater depth in the mantle. O'Hara (*Nature*, **243**, 507;

1973), on the other hand, criticised this view on the grounds that the data could as easily be explained in more conventional terms. He pointed out that the geochemical variations radiating from Iceland could be caused not by the mixing of two primary magmas but by differential fractional crystallisation of material from a single source; and he now (in *Nature*, **253**, 708; 1975) reiterates, clarifies and expands the arguments in support of his case.

In his original article O'Hara seemed to imply that a choice would have to be made between two mutually exclusive models. He now suggests that fractional crystallisation and a mantle plume might be compatible under certain circumstances but that, if they are, Schilling's particular interpretation involving relatively undepleted plume material must certainly be ruled out on grounds of density alone. Schilling, however, continues to stick to his own model involving a plume "made of slightly lighter and more primordial material"; and he and Noe-Nygaard (*Earth planet. Sci. Lett.*, **24**, 1; 1974) have now extended the investigation to cover variation in the behaviour of the Icelandic plume with time.

In the light of Schilling's view that the plume comprises material chemically and isotopically distinct from that of the asthenosphere (which is penetrated by the plume from below), Schilling and Noe-Nygaard envisage three different types of plume–ridge relationship. Their 'normal ridge segments' (NRS) remote from any plume have normal ridge elevation, well developed and symmetrical magnetic anomalies and typical oceanic crustal thickness and structure. The material rising to form new lithosphere (in response to spreading rather than as a cause of it) is derived from the asthenosphere, and the resulting basalts are tholeiitic, depleted in large ionic lithophile elements and low in radiogenic isotopes, and have $(La/Sm)_{EF}$ ratios <1.

The 'plume ridge segments' (PRS) directly over plumes have higher elevation, branching aseismic ridges or island chains, crustal thickness and structure intermediate between the typically oceanic and typically continental, and higher geothermal gradients. Here plume material is forced into the gap left by diverging plates, usually in quantities sufficient to more than fill the gap and thus allow the accumulation of plateau basalts and the formation of anomalously thick oceanic crust. In this situation new lithosphere over a PRS will be derived entirely from the plume, will have $(La/Sm)_{EF}$ >1 and will have radiogenic isotopes characteristic of the particular plume. But when and if the plume flux decreases to below the quantity required by the diverging plates, asthenospheric

material will mix with the plume material leading to hybrid lavas with intermediate $(La/Sm)_{EF}$ values and radiogenic imprinting. Finally, there are also 'transitional ridge segments' (TRS) between NRS and PRS, but for the time being these are ignored because of their complexity.

With this model (NRS and PRS only) in mind, Schilling and Noe-Nygaard have investigated the rare earth element (REE) chemistry of the 3,000 m thick lava sequence in the Faroe Islands. This pile of plateau lavas contains two clear marker horizons which define a series of aphyric quartz tholeiites (lower), a series of porphyritic quartz tholeiites (middles) and a series of olivine tholeiites (upper). The geochemical study shows that, with the exception of one flow in the middle series, all the flows of the lower and middle series have light REE enrichment with $(La/Sm)_{EF}>1$. By contrast, the flows of the upper series fluctuate rapidly between REE depletion with $(La/Sm)_{EF}<1$ and REE enrichment, ending (at the top) with flows predominantly depleted. Schilling and Noe-Nygaard claim, giving reasons, that this two-component pattern cannot be attributable to differing fractional crystallisation or partial melting. They argue instead that the data support their two-source model. The lower and middle series are plume-derived, with the exception of the anomalous middle series flow which marks the first appearance of asthenospheric material. In the upper series there are rapid

changes between flows mostly plume-derived and flows mostly asthenosphere-derived, with the most recent activity being mainly of the latter type.

But why did the change from plume material to largely asthenospheric material take place? There are two possibilities within the scope of the Schilling–Noe-Nygaard model; either the plume must have decreased in intensity or the spreading rate at the ridge must have increased, thereby allowing the asthenosphere to acquire greater influence. According to Tarling and Gale (*Nature*, **218**, 1043; 1968) the ages of the Faroes basalts lie between 60 and 50 million years, and according to Vogt and Avery (*J. geophys. Res.*, **79**, 363; 1974) spreading in the area was decreasing rapidly at that time. The intensity of the plume must therefore also have decreased rapidly. Before it did, however, spreading rate and the flow REE chemistry were comparable to those relating to Iceland during the past few million years, which suggests that the plume intensities then and now were similar. This, in turn, would imply that the plume intensity went through a minimum some time between 50 and 10 million years ago.

Insofar as so very little is known about the origin of supposed mantle plumes and the conditions of their existence, there is presumably no basis for ruling out such temporal variations in plume intensity. On the other hand, in view of the large inertia of thermal systems of the required size, it may be difficult to understand how a plume envisaged as a continuous jet of material could vary in intensity quite so rapidly as the geochemical properties of the Faroes basalts imply. One way in which the REE data and a continuous plume could be reconciled would be to postulate sudden rift jumping and tapping of asthenospheric material at the plume margin, but there is apparently no observational support for this. Schilling and Noe-Nygaard therefore propose that mantle plumes may not be continuous jets at all but may arise as a series of discrete blobs or diapirs. This makes rapid flux variations in space and time much easier to visualise, especially if the rising blobs were to taper downwards rather as inverted liquid droplets.

Reducing exposure of tissues to contraceptives

from our Steroid Biochemistry Correspondent

SINCE the late 1950s when steroids were first used as oral contraceptives many variations in the nature of the steroid

employed, the mode of administration and the dose administered have been tried in order to increase the acceptability of hormonal contraceptives and to eliminate possible side-effects But the fact that the steroids enter the general circulation means that tissues other than those concerned with the control of fertility are exposed to the biologically active compounds, and often for long periods of time In order to overcome these disadvantages the possibility of obtaining an antifertility effect by a more direct action of the steroid on tissues of the reproductive tract, with a consequent reduction in the systemic effect, has been investigated

One interesting development uses the advantageous features of an intra-uterine device and low-dose progestogen contraception (Pharriss *et al*, *Fertil Steril*, **25**, 915–921, 1974) This intra-uterine device is made of an ethylene copolymer in the shape of a T, the stem of which is hollow and contains a suspension of microcrystals of pro-gesterone The rate of release of pro-gesterone from the device is controlled by the ethylene copolymer membrane Initial trials suggested that a pro-gesterone release rate of 65 μg per day was sufficient to provide a contraceptive effect This amount of progesterone is equivalent to only a small proportion of the daily production rate during the luteal phase of the menstrual cycle The present report gives details of the use of this device by more than 3,000 women for more than 25,000 women-months of treatment The efficacy and use effectiveness of the device compared favourably with that of other methods of contraception The preg-nancy rate was only 1% compared with a rate of 18% for a similar T-shaped device not containing progesterone A T-shaped device was used because of its acceptability, easy insertion and re-moval and low natural expulsion rate

This method of contraception has other advantages the active compound is delivered directly to the target tissue and the low release rate of the natural ovarian hormone is unlikely to produce any systemic effect even if any enters the general circulation The sloughing of the endometrium at menstruation prevents an accummulation of the steroid in this tissue In investigations with monkeys using devices containing isotopically labelled progesterone it was shown that some radioactivity did enter the circulation but since the uterus is known to metabolise progesterone it seems that this radioactivity is more probably associated with biologically inactive metabolites than with pro-gesterone itself The total plasma radio-activity remained constant over a one-year period showing that a relatively constant release rate of pro-

gesterone from the device was obtained As with other intrauterine devices this system has the advantage that it does not require any active involvement by women using it

An alternative approach to the problem of reducing the continuous exposure of the tissues to the contra-ceptive steroid involves the administra-tion of a synthetic progestogen at the middle of the menstrual cycle before endogenous progesterone secretion com-mences (Sakiz *et al*, *Contraception*, **10**, 467–474, 1974) In this way the synthetic steroid blocks the pro-gesterone receptors in the uterus and prevents endogenous progesterone from inducing those changes in the uterus which are necessary for implantation to occur In a trial involving 140 women who completed 1,362 treatment cycles, 50 mg of the progestogen ethylnorges-trienone was administered on days 15, 16 and 17 of the menstrual cycle The method proved to be an acceptable form of contraception for most women and many of the minor side-effects seen with other hormonal contraceptives seemed not to occur But there was a failure rate of 9 6 per hundred women years which is too high to be accept-able, about half of these pregnancies were considered to be due to method failure One difficulty of the method is determining the time of ovulation pre-cisely since ideally the progestogen should be administered immediately after ovulation The approach seems however to be a promising one

IgE and immunity to schistosomiasis

from F E G Cox

ONE of the characteristics of the immune response to most infections caused by parasitic worms is the pro-duction of large amounts of IgE It has been speculated that this immuno-globulin (which is associated with various allergies but does not seem to have any beneficial role) originally evolved as an integral part of the immune response to helminths Until recently there has been little real evi-dence to support this hypothesis and theories of immunity to helminths have relegated IgE to a subsidiary role All observers agree that the mechan-isms by which animals rid themselves of worms and resist further challenge are complex but attempts to tie all the available experimental evidence to-gether in a single coherent story make the mechanisms very difficult to com-prehend It is tempting to use all the known facts and to postulate mechan-isms involving cell-bound IgE, serum immunoglobulins, lymphocytes, mye-

loid cells, macrophages, complement and various pharmacologically active substances to account for the immune response

Much of what we know about helminth immunity is based on experi-ments with various nematodes, parti-cularly *Nippostrongylus brasiliensis* in the rat The immune response seems to proceed in three steps damage by anti-body, a cell-mediated response and, finally, myeloid cell degranulation and the production of 5-hydroxytryptamine and histamine which leads directly to the expulsion of the worms The final stage is the one that involves IgE and thus homocytotropic antibody is probably not directly concerned with damage to the worms but plays a peri-pheral part in the development of immediate hypersensitivity Apparent confirmation of this peripheral role comes from the work of Jarrett and Bazin (*Nature*, **251**, 613, 1974) who used the recently available purified rat IgE from myelomas as a reference against which to measure total IgE concentrations in animals infected with *N brasiliensis* They concluded that the bulk of the IgE is surplus to the concentrations expected against known antigens and probably results from potentiated responses to miscellaneous unknown antigens to which the animals had previously become sensitised

In schistosomiasis it now seems that IgE has a central role in the immune response All investigators agree that the stage in the life cycle most sus-ceptible to the immune response is the schistosomula, the young form that penetrates the skin and migrates to the blood vessels in which the adult develops Clegg and Smithers (*Int J Parasitol*, **2**, 79, 1972) demonstrated convincingly that the schistosomula of *Schistosoma mansoni* were killed *in vitro* in the presence of IgG and complement components from immune rhesus monkeys and Capron *et al* (*Int J Parasitol*, **4**, 613, 1974) have found similar cytotoxic activity in humans Antibody-mediated damage can there-fore be regarded as the first step in the immune response to schistosomiasis as in *N brasiliensis* infections

Various kinds of cell have been shown to be involved in immunity to schistosomiasis and it is difficult to determine the actual role of each type Dean, Wistar and Murrell (*Am J trop Med Hyg*, **23**, 420, 1974) have found that rat neutrophils damage schisto-somula *in vitro* by direct contact and by enzymic activity IgG is involved in the attachment of the cells to the worms and complement also seems to play a part in this process although its role is not proven Complement-independent killing of schistosomula by mixed "polymorphonuclear and mono-nuclear" leukocytes has been achieved

by Butterworth, Sturrock, Houba and Rees (*Nature*, **252**, 503, 1974) These authors found that schistosomula were damaged in the presence of normal leukocytes and sera from immune patients The nature of the cells and antibodies involved is not disclosed but it is suggested that cytotoxicity is associated with eosinophils

So far neutrophils and eosinophils have been suggested as effector cells in the immune response but the most recent work in this field also implicates macrophages Capron, Bazin, Dessaint and Capron (*Nature*, **253**, 474, 1974) found that normal rat macrophages adhered to schistosomula in the presence of immune sera *in vitro* Absorption of the immune sera with various anti-rat-immunoglobulin sera showed the immunoglobulin involved to be IgE Further experiments showed that the IgE was specific to the parasite, that macrophage adherence played a part in the killing of schistosomula and that complement was not required for the killing Killing requires the presence of specific IgE which binds normal macrophages to the surface of the worm and, although it may contribute directly to the death of the worm, the main importance of this binding is that it is instrumental in enhancing the lethal effects of immune IgG These experiments draw attention to the possibility of IgE-mediated macrophage adherence in other situations and at last provide a central rather than a peripheral role for IgE in immunity to helminth infections Perhaps we will soon know what IgE really does other than cause asthma and hay fever

Peptidoglycan and the immune response

from a Correspondent

THE bacterial envelope is comprised of the cytoplasmic membrane and the outer cell wall The classic division of bacteria on the basis of the Gram stain turns out to correspond exactly to variations in the chemistry and structural organisation of the outer part of the envelope But in spite of the variations there is a unique component, the peptidoglycan, present in greater or lesser amount in the cell wall of all bacteria The peptidoglycan matrix is built up from strands of chitin-like polysaccharides but with every alternate sugar residue being N-acetylmuramic acid (the 3-O-D-lactic acid ether of N-acetylglucosamine) The acid residues are substituted by amide linkages with short peptide side chains and many of these chains are joined to link adjacent polysaccharide strands together in a meshwork In most—per

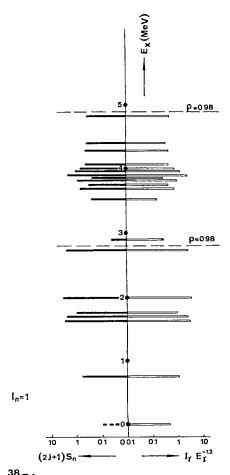
haps all—gram negative bacteria and in several gram positive bacilli the peptidoglycan structures differ chemically only in detail although it seems probable that their three dimensional arrangements vary considerably Outside this range of organisms the chemical differences, particularly in peptide structure, multiply enormously

All this has been known for several years It is therefore surprising that so little is known about the effects of the ubiquitous peptidoglycan on mammalian cells Most people are in contact with bacterial peptidoglycan from very early life Certainly peptidoglycan is immunogenic and there must be a continuous stimulation of the immune response by bacteria indigenous to the respiratory and gastrointestinal tracts

And peptidoglycan is of course a component of complete Freund's adjuvant—the suspension of tubercle bacilli which, injected as a water-in-air emulsion with antigen, greatly enhances the immune response to many antigens Does peptidoglycan play any part in adjuvanticity? It now seems clear that it does

Purified peptidoglycan enhances antibody production and induces delayed-type hypersensitivity at rather lower concentrations than those of the whole bacilli used in Freund's adjuvant There is a fascinating argument going on between two French laboratories about the minimum structural features of peptidoglycan necessary for the adjuvant effect Lederer and his colleagues Adam, Ciorboru Ellouz and Petit (*Biochem biophys Res Commun*, **59**, 1317–1325, 1974) have taken degradation fragments of peptidoglycan from *Mycobacterium semeqmatis* or *Escherichia coli* and found that a monomeric fragment N-acetylglucosaminyl (β1, 4) N - acetylmuramyl - L - alanyl - D - isoglutaminyl - meso - diaminopimelyl - D - alanine can replace whole killed mycobacteria or undegraded peptidoglycan Furthermore the terminal N-acetylglucosaminyl and D-alanyl units can be removed without loss of adjuvanticity A synthetic compound, N-acetylmuramyl-L-alanyl-D-isoglutamine turns out to be at least as active as the monomeric unit but a synthetic disaccharide-L-alanyl derivative is inactive So are the hexosamine free di- to tetra peptides Lederer concludes that the glycopeptide linkage and D-isoglutaminyl unit are indispensable for an adjuvant effect

Nauciel and Fleck (*C r Acad Sci Paris*, **276D**, 3499–3500, 1973, *Nature*, **250**, 517–518, 1974, *Eur J Immun*, **4**, 352–356, 1974) disagree on the first point but support the importance of D-isoglutamine They find that the peptide subunit alone possesses the same adjuvant activity as intact peptidoglycan at least in delayed-type hypersensitivity

reactions to azobenzenearsonate-N-acetyl-L-tyrosine


In a search for other points in the immune response at which peptidoglycan might function, the inhibitory effect of this substance on macrophage migration (Heymer *et al*, *J Immun*, **116**, 1743–1754, 1973) is relevant This effect seems to be distinct from migration inhibition of macrophages mediated immunologically by factors secreted by activated lymphocytes A direct action of peptidoglycan on the macrophage surface is possible but little is known as yet about the structural features responsible for this interesting effect

Finally, stimulation of graft rejection —for example of tumour cells—by *Mycobacterium tuberculosis* BCG has been studied by Zbar *et al*, (*J natn Cancer Inst*, **48**, 831–835, 1972), using isolated mycobacterial cell walls The effect is complex and, at least in the systems in which virally induced tumours were studied, stimulation of host interferon production by the mycobacterial adjuvant is possible But this presumably is not involved in host rejection of chemically induced tumours Could a lectin-like activity of antibodies directed against the polysaccharide part of peptidoglycan be involved in host reactions against tumour cells? Several lectins that agglutinate tumour cells (for example, wheat germ agglutinin Allen and Neuberger, *Biochem J*, **135**, 307–314, 1973) interact with an N-acetylchitobiose unit that is found commonly in mammalian glycoproteins, and also bind bacterial peptidoglycan containing an analogous repeating disaccharide unit In some interesting experiments Shier (*Proc natn Acad Sci USA*, **68**, 2078–2082, 1971) prepared antisera against a synthetic antigen containing N-acetylchitobiose hapten groups His finding that these antibodies show some antitumour effects therefore raises the interesting question whether antibodies of similar specificity raised in response to peptidoglycan mimic this reactivity

Single-particle states of nuclei

from P E Hodgson

MUCH of our knowledge of atomic nuclei has been obtained by studies of reactions that remove one nucleon from the nucleus or add one nucleon to it Analysis of the cross sections of these interactions gives the quantum numbers and the occupation probabilities of the single-particle states of the simple shell model This is a very basic feature of nuclei, and it is related to many other nuclear properties such

^{38}Cl

Fig. 1 Comparison between the stripping strengths $(2J+1)S_n$ for the reaction ^{37}Cl(d,p)^{38}Cl to many states of ^{38}Cl (solid lines) and the reduced transition probabilities after thermal neutron capture ^{37}Cl(n,γ)^{38}Cl (open lines) Only the transitions with orbital angular momentum transfer $L_N=1$ are included The (n,γ) partial radiation widths were normalised so that their largest value equals the corresponding $(J+1)S_n$ values The correlation coefficients are given for levels up to 2 8 MeV and for all levels

as their charge and matter distributions, electromagnetic transition rates and quadrupole moments

The theories used to analyse the experimental data, in particular the distorted wave theory, involve certain approximations and are subject to some assumptions that together limit the accuracy of the final results The formalism contains some purely mathematical approximations, and physically there are for example uncertainties connected with the possible contribution of compound nucleus and two-step reaction processes Some improvement in the accuracy of these analyses has recently come from the use of the j-dependent sum rules (*Nature*, **249**, 695, 1974) More recently Clement in a contribution to a conference on nuclear structure and spectroscopy held last year in Amsterdam has drawn attention to the importance of comparisons between the (d,p) stripping and the neutron capture data

The (d,p) deuteron stripping reaction and the (n,γ) neutron capture reaction both deposit a neutron in one of the unoccupied states of the final nucleus, and so both should give the same result for the structure of a particular nucleus The important quantities are the spectroscopic factors that measure the single-particle strengths of the states in the final nucleus and the corresponding transition probabilities for neutron capture Comparison of the numbers obtained for the same nucleus by the (d,p) and (n,γ) reactions is thus a good test of the reliability of both analyses

Such a comparison was made for ^{38}Cl by Spits and Akkermans (*Nuclear Physics,* **A215**, 260, 1973) They measured the cross section for the ^{37}Cl(n,γ)^{38}Cl neutron capture reaction to many states of ^{38}Cl and compared the transition probabilities they obtained from their data with the spectroscopic factors found from the corresponding ^{37}Cl(d,p) ^{38}Cl deuteron stripping reaction by Engelbertink and Olness (*Phys Rev*, **C5**, 431, 1972) The results are compared in Fig 1 and show a remarkably high degree of correlation between the two sets of numbers Indeed if the data are analysed statistically the correlation coefficient between the two sets is as high as 98%

Similarly high correlations have now been obtained for a whole series of nuclei, a few cases of low correlation being readily explicable as due to the presence of nearby resonances The result for ^{38}Cl is thus not an isolated example, but is quite typical

These astonishingly high correlations between spectroscopic factors obtained by quite different reactions validate at a stroke essentially all the significant approximations and assumptions in the theories of deuteron stripping and neutron capture (Kopecky, Spits, and Lane, *Phys Lett*, **49B**, 323, 1974) The reaction mechanisms are so different that it is inconceivable that any perturbing factor in the analysis should have the same effect in the two reactions The excitation energies of the compound nuclei in the two cases differ widely, so the compound nucleus cross sections must be different and since they do not affect the results they must both be small Similarly for the two-step contributions (*Nature*, **247**, 179, 1974) which must be quite different in the two types of reaction All perturbing factors, if important, could only reduce the correlation coefficients and since they are so high the analysis provides strong evidence that both sets of analysis are rather more accurate than has been generally believed This very satisfactory result should be a welcome stimulus to further analyses of single particle states in nuclei

New method of determining nuclear quadrupole moment

from P E Hodgson

THE recent theoretical work of Clement (*Nuclear Phys*, **A213**, 492, 1973) on the nuclear shell model has made it possible to express the nuclear quadrupole moment in terms of single particle quadrupole integrals and the spectroscopic factors extracted from single proton transfer reactions In some cases all the required data are available and the resulting values of the nuclear quadrupole moment are in excellent accord with those determined by atomic methods

In a previous note (*Nature*, **249**, 695, 1974) the work of Clement and Perez on the j-dependent sum rules was described This shows how the spectroscopic factors for stripping and pickup reactions on the same nucleus can be related to each other, thus providing multiple checks of the values obtained for the spectroscopic factors and confirming the validity of the distorted wave theory used to obtain them If all the necessary data are available, the spectroscopic factors can be obtained with an accuracy of better than 10%

The single-particle quadrupole integrals are simply overlap integrals of two single-particle wavefunctions with the quadrupole operator These may be evaluated very easily using harmonic oscillator wavefunctions, but the results are rather inaccurate, especially for valence nucleons Much better results can be obtained with single-particle wavefunctions evaluated as the eigenfunctions of a Saxon–Woods potential with parameters adjusted to give the correct binding energies, these can now be obtained easily with an electronic computer

Thus for nuclei for which a complete set of data are available it is possible to use the formalism of Clement to calculate the quadrupole moment

Clement and Perez (*J Phys*, **A7**, 193, 1974) have now done this for ^{37}Cl, and find $Q = -0\ 057 \pm 0\ 005$ barn which compares very well with the atomic value $Q = -0\ 062$ barn, showing the reliability of the method As more spectroscopic factors become available this should become a powerful method of determining nuclear quadrupole moments, which will be especially useful in cases where the atomic value is not easily obtained

Diode molecules

from our Moleculai Physics Correspondent

NOT many years ago a distinguished theoretical chemist deliberately left the field, explaining that an important factor in his decision to work elsewhere was the strong possibility, as he conceived it, that no further, totally new and astonishing phenomenon might ever again be discovered at the purely molecular level Premature as this may have been at the time, and counter-indicated as it may seem by subsequent events—for example in the area of laser photochemistry—it remains broadly true that, in spite of remarkable advances in instrumentation and the mastering of known effects in ingenious ways, the incidence of altogether new ones in the molecular world could be said to have lagged behind the steady stream of named, prizewinning, conference-engendering effects in other subjects Having said which, one may as reasonably remark that refuge from pessimism can be sought in the ill-defined yet compelling suspicion that what does remain to emerge from the fastnesses of undiscovered molecular behaviour may prove to be very spectacular indeed

A sound conjecture—because in a way a truism—is that radically new effects are likely to involve some form of electromagnetic, probably time-dependent phenomenon Stimulated emission fitted this description, the widely publicised speculations about molecular superconductivity are a long shot in the same direction where the merest vestige of an effect would be altogether sensational

Closer to Earth, yet of undoubted promise, is the recent speculation by Arieh Aviram and Mark Ratner (*Chem Phys Lett*, **29**, 277, 1974) that it should be possible to design molecular rectifiers by careful patching together of suitable donor and acceptor subsystems The key to this idea is that, by bridging an acceptor unit, perhaps a quinone-like ring system, by a σ-bonded hydrocarbon bridge to an electrophobic unit, perhaps containing methoxy-groups, the necessary current–voltage asymmetry could be achieved Actually more exotic candidates for donor and acceptor are available and might be tailor-made for the task, with the passive bridge playing an essential part both in providing rigidity and keeping donor and acceptor at arm's length —just out of range of direct level-interactions, though not of tunnelling transfer

No doubt these bare ideas will need considerable testing and elaboration before it can be claimed that rectifier action is a practical possibility But, showing admirable willingness to back their level diagrams with some real mathematics, Aviram and Ratner go on to present a careful perturbational calculation of the current–voltage characteristics of a plausible rectifier structure (actually a simple hemi-quinone) This is semi-quantitative quantum mechanics at its best, using relatively crude approximations to warrant an idea and point to further refinements When the necessary matrix-elements are computed, with reasonable assumptions of ionisation energy and electron affinity, the I–V characteristic is indeed of the form predicted, with an appreciable asymmetric barrier to conduction

Needless to emphasise, far too much is left to good fortune for the results to approach a theoretical 'proof' of viable rectifier action Direct electrode-electrode tunnelling could swamp the whole effect, the complex problems of metal–organic junctions and crystal field effects have yet to be built in— each might either enhance or kill off the desired effect Yet the work described has a convincing air of the *premier pas qui coûte* and we may well hear a lot more of the molecular rectifier, perhaps the absolute ultimate in electronic miniaturisation

Volcanoes and ice ages

by John Gribbin

ACCORDING to Kennett and Thunell (*Science*, **187**, 497, 1975) "volcanic ash in deep-sea sections indicates very high rates of explosive volcanism during the last two million years" This apparent global increase in Quaternary explosive volcanism flies in the face of some cherished geophysical beliefs—but it offers a new insight into the widespread and frequent glacial activity that has occurred over the same period

Simple tectonic theory would suggest that volcanic activity is related to local events—collisions between blocks of crust which lead to mountain building But it now seems from study of 320 deep-sea sections drilled around the world during the Deep Sea Drilling Project that there has been a much higher rate of explosive volcanism from both island arc and 'hot spot' volcanoes during the past 2 million years than the 'normal' level of the past 20 million years And, as Kennett and Thunell point out, "increased Quaternary volcanism coincides approximately with that episode of the Cenozoic marked by major and rapidly fluctuating climatic change"

Just how these two effects may be related remains to be unravelled, but several interesting possibilities are raised First, it is well established that under appropriate conditions the spread of volcanic dust in the atmosphere caused by a marked increase in volcanic activity could trigger the onset of an ice age The dust simply acts as a veil blocking some of the Sun's heat, and if the resulting cooling lasts for long enough for ice cover to become established it may take more than the removal of the dust veil to melt the ice, because the ice's high albedo will continue to ensure that little solar heat is absorbed

But studies of shorter stretches of the geological record than the 20 million year sample of the DSDP show that although widespread volcanic activity often precedes the spread of the glaciers it is possible either for glaciation to occur without any increase in volcanic activity, or for there to be an increase in volcanism without immediate climatic repercussions This encourages speculation that there are one or more additional mechanisms of key importance in triggering ice ages The Milankovitch model, in which phases of cooling are produced by changes in the orientation of the Earth and by 'stretch' of its orbit around the Sun is perhaps the most attractive of these mechanisms, especially in the form in which Kukla has recently presented it (*Nature*, **253**, 600, 1975) To my mind, the most plausible overall model of ice ages is that when the northern hemisphere is at its coolest phase of the astronomical Milankovitch cycle, conditions will be appropriate for ice cover to develop dramatically if some further effect—such as volcanic activity—provides the final trigger

But the model can also be turned on its head The repeated loading and unloading of the Earth's crust caused by the advance and retreat of the glaciers might, in fact, trigger increased volcanic activity And, if each of these processes occurs there could be a snow-ball effect by which a small climatic fluctuation becomes a full-scale ice age

Whatever the truth of the matter, these new discoveries emphasise the impossibility of trying to deal with problems in the earth sciences within rigid compartments The development of plate tectonic theory has already contributed greatly to the study of past climates by explaining how the present state of the globe, with a nearly land-locked North Polar Ocean, differs from the situation in earlier times when the continents were distributed differently and ice ages were extremely uncommon (see page 14 of this issue of *Nature*) And at a more immediately important level, it seems that a better understanding of volcanism, as well as a better understanding of ocean currents and other aspects of earth science, will be an essential prerequisite to a really satisfactory theory of climatic change

Tilt and strain monitoring of the 1974 eruption of Mount Etna

G. Wadge, J. A. C. Horsfall & J. L. Brander

Geology and Geophysics Departments, Imperial College, London SW7, UK

Using advanced modern equipment capable of continuous monitoring it has been possible to measure the degree of tilt and strain undergone by Mount Etna during a recent phase of volcanic activity The results are open to interesting interpretation, and the model suggested here, though hypothetical, is quite plausible geologically

THE measurement of tilt and of distance have proved valuable techniques in the surveillance of volcanic activity[1] The interpretation of the observed deformation associated with a small eruption in January–March, 1974, gives some insight into the eruptive mechanisms operative on Etna, and also provides some indication of the potential of geodetic techniques for the prediction of activity on that mountain

The tilt transducer used in this study was an Autonectics biaxial borehole tiltmeter consisting essentially of a circular spirit-level mounted at the bottom of an aluminium alloy tube (Fig 1) Tilt changes were monitored using a pair of a c resistance bridges which gave an output proportional to the position of the bubble in two orthogonal axes These voltages were recorded on a two channel Rustrak chart-recorder with bias-steppers which gave an effective increased chart width[2] The system was powered by alkaline-manganese cells, and to conserve power the tiltmeter was run for three 1-min intervals in every hour Sampling intervals were timed by an Accutron clock and the time scale of the record was derived by dividing the length of the record by the total number of days elapsed

The tiltmeter was installed in a borehole 1 5 m deep in ash (Fig 2), 3 km south of the Central Crater The instrument was levelled using an oscilloscope with its horizontal and vertical inputs connected to the tiltmeter outputs, the top of the tiltmeter tube was then moved manually to centralise the spot on the screen[3]

On January 30, 1974 a small flank eruption began on the western side of Etna[4], and during two eruptive periods (January 30–February 16 and March 11–29) produced two small pyroclastic cones and approximately 6×10^6 m^3 of lava (Fig 2) The correlation between the tilt record and this eruptive cycle is clear, detailed and apparently free of spurious effects The following volcanological interpretation is based on the assumption that a positive change in the radial component indicates inflation of the summit region The records of both the radial and tangential components of tilt during the 10 months of monitoring show very similar patterns of change (Fig 3)

The tilt record of the period before January 1974 is very quiet, but about three weeks before the eruption (the two phases of which are represented by 1-2 and 3-4 in Fig 3), the summit inflated and a small but regular fluctuation of tilt began Two weeks before the eruption started the radial component recorded a series of very sharp though small deflations (Fig 3ci) which gave way to a series of large amplitude fluctuations (Fig 3cii) up to and immediately following the start of eruptive activity The onset of the initial deflations corresponds closely with the start of the seismic activity that was felt at the volcano, and is interpreted as an expression of the initiation of fracture propagation from the magma reservoir at the summit to the eruption site on the western slopes The large amplitude tilt fluctuations (Fig 3cii) are cycles of rapid inflation followed by deflation of the summit and could represent the pulses of magma moving into the flanks of the volcano Careful examination of the record shows that in most cases deflation was more rapid than the inflation, particularly for the tangential component It may be possible

Fig 1 Diagrammatic cross section of the tiltmeter installation

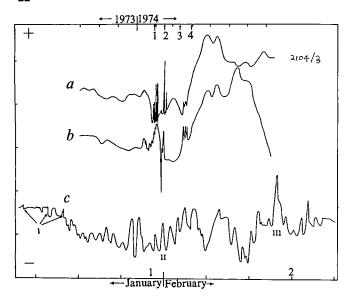
Fig 2 Sketch map showing the location of the tiltmeter with respect to the eruption site and the Central Crater


Fig 3 Tiltmeter record for the period September 28, 1973–August 8, 1974 *a, b*, Smoothed traces of the record (sampled at weekly intervals), for the whole period, indicating the tilt variations in directions radial (*a*) and tangential (*b*) to the Central Crater at the summit of Etna *c*, The non-smoothed trace of the radial component during and just before the first phase of the eruption The scale of the abscissa for the two curves *a* and *b* is at monthly intervals, for *c* at 5-d intervals The interval of the ordinate is 50 m rad (equivalent to a change in elevation of 5 cm km^{-1}), and the positive sense of tilt change shown is summit up (*a*), and ENE up (*b*)

to correlate these magma pulses with specific events in the vent activity The particularly large tilt changes just before the end of the first phase of activity (Fig 3*ciii*) coincided with a brief rejuvenation of effusive activity which produced three new lava flows[4]

A period of calm characterised the tilt record for the interval between the two eruptive episodes during which the summit remained deflated The degree of tilt that marked the start of the second phase was relatively minor compared with that of the first phase and is interpreted as indicating that the magma moved from the summit along the same conduit as that formed during the previous activity The marked decline in vent activity and the rapid, smooth summit inflation on March 23 presaged the closing of the conduit and the end of the eruption

The summit inflated throughout April and early May and then remained stable to the end of the record The gradual tilt change in the tangential component during July and August 1974 cannot be interpreted as yet The sense of this change—west(eruption) side down when the summit rose and vice versa—is unexpected, but could be because deflation of the western slopes complemented the inflating summit[5]

The most striking feature of the record is the consistent frequency of the tilt fluctuations—one fluctuation a day—during and just before the eruption, a feature that is not evident during the non-eruptive periods It suggests some non-volcanic causal mechanism such as, possibly, earth tides

Since October 1971, precise electromagnetic measurements of distance have been made periodically on a network of 19 permanent benchmarks arranged in 2 concentric rings around the summit of the volcano (Fig 4) Early surveys were made with the National Physical Laboratory Mekometer III prototype[6] but since 1973 a Hewlett-Packard 3800B has been used

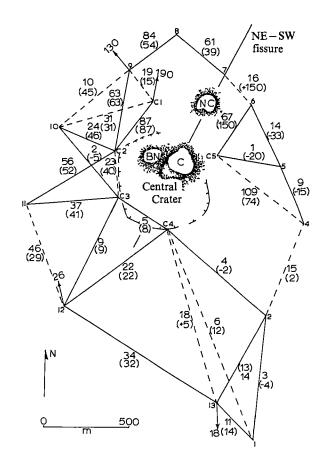
Up until June 1973 the measurements showed changes of up to 310 mm in the lengths of the lines on the summit network They are interpreted as showing that the summit region was inflating elastically[7], although the Mogi model[8]—used to explain the deformation of Kilauea[9]—does not agree with the observations The model which best describes the observations is that in which a vertical cylinder of infinite length but finite diameter expands in an elastic half-medium[7,10] The displacements of all of the points in the half-medium are inversely

proportional to the square of their distance from the cylinder axis and are directed radially outwards from it The length changes observed up until June 1973 gave excellent best-fit agreement with the changes which could be expected were such a cylinder 200 m in diameter located beneath the North-east Crater (Fig 4) Exceptions to this model occur on the lines involving stations 9, C1 and 13 (Fig 4) which are situated on very recent flows and seem to have moved downslope after the apparent solidification of the lava

The changes observed on the summit network between June 1973 and August 1974 (Fig 4) do not fit such a simple model as the earlier changes

Theoretical models

The model which best fits these results involves two cylinders one expanding and situated as before beneath the North-east Crater, and the other—of the same diameter—contracting and centred on the Chasm (the figures given by the model are shown in brackets in Fig 4) The contracting cylinder would not affect the lines on the eastern side of the NE–SW tranding fissure, the most important tectonic feature of the summit area[11] Anomalous movements again affect stations 9, C1 and 13, and the probable displacement vectors are shown in Fig 4 Similarly, station 12 seems to have moved anomalously, though this is not understood

The complexity of this model cannot be denied, but the volcanological interpretation of the cylinders is simple


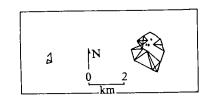


Fig 4 The summit region of Mount Etna C, The Chasm, BN, the Bocca Nuova—both of which are surface expressions of the Central Crater, NC, the North-east Crater Geodetic benchmarks shown by small numbers Solid lines, distances that increased, broken lines, those that decreased, unbracketed numbers, the observed changes of distances (mm) from June 1973 to August 1974 Bracketed numbers, changes (mm) expected from the model described in the text Displacement vectors for the four anomalous stations are also shown
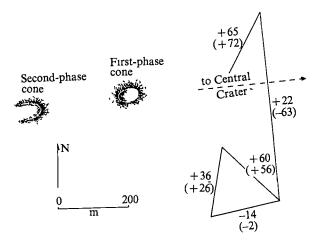

Fig. 5 The site of the January–March, 1974 eruption on the western flank of Etna, showing the first phase (January–February) cone, the second phase (March) cone, and the geodetic benchmarks Unbracketed numbers, distance changes (mm) observed between February and August 1974, bracketed numbers, changes of length (mm) expected from the model described in the text Inset, geography of the two networks

The continuous effusive activity which characterised the North-east Crater for many years stopped abruptly during the 1971 eruption[11] It thus seems that before 1971 the North-east Crater had acted as a safety valve to the continuous movement of magma from below but that since then pressure has built up beneath a blockage in the conduit

In contrast, the contracting cylinder part of the model indicates the reverse process, the decrease of pressure on the western side of the Central Crater, caused by the removal of magma from the conduit beneath the Chasm

During the February phase of the 1974 eruption precise distance measurements were made on a small network of benchmarks in the immediate vicinity of the eruption site, they were repeated in August 1974 The changes between the measurements are shown in Fig 5 as unbracketed numbers A contracting cylinder model like that applied to the Chasm,

but of 50m diameter, situated beneath the first-phase cone agrees quite well with the observed changes This can be improved, however, by including the influence of a horizontal cylinder which joins the first-phase cone to the Central Crater and which contracts by one-fifth the amount of the vertical one The observed and expected changes of line 1–3 disagree, however (Fig 5)

How the models fit

The vertical cylinder could represent the first phase vent, and the horizontal cylinder the feeder conduit from the Central Crater to the eruption The contraction of the cylinders indicates the decrease of magmatic pressure which accompanied the cessation of effusive activity The anomalous change in length of line 1–3 indicates that the feeder conduit (which passes directly beneath the line) widened inelastically during the second phase of the eruption

The deflation of the western side of the summit region and of the horizontal cylinder used to model the deformation to the east of the eruption site suggests strongly that the eruption was fed by a conduit (dyke?) from the Central Crater This view is endorsed by the evidence of a narrow line of micro-earthquakes along the proposed path of the conduit during the activity (G Luongo, personal communication) and by the sympathetic behaviour of the Bocca Nuova[12] which suggests that the conduit originated there

The 1974 eruption seems to have relieved the stress on the western side of the Central Crater but not that to the north around the North-east Crater, the continued inflation in that area must make it a likely place for renewed activity In fact, since the last measurements were made quiet effusive activity has broken out at the foot of the North-east Crater (October 1974)

Magnetic field in the intergalactic region

Jacques P. Vallée*

David Dunlap Observatory, University of Toronto, Canada

An analysis of the redshift dependence of the rotation measures (RM) and of the intrinsic position angles of the polarised radiation of radio galaxies and QSOs is made The results place an upper limit of 10 rad m^{-2} to the observed RM, coming from the contribution of the magnetic field in the intergalactic region

* Present address Sterrewacht, Huygens Laboratory, Leiden 2405, The Netherlands

FARADAY rotation in a plasma produces a rotation of the plane of linear polarisation of the radio emission, the rotation increasing proportionately to the square of the wavelength The proportionality factor is called the rotation measure (RM), and depends on the product of electron density, magnetic field, and path length inside the plasma The plasma in the radio source gives rise to the source RM Any intergalactic plasma will also contribute, the extragalactic RM is defined here as the observed RM minus the contribution from our

Fig 1 The redshift dependence of $F(q_0,z)$ for various values of the cosmological deceleration parameter q_0 Numbers on curves indicate values of q_0

Galaxy It follows that, setting z_s as the source redshift,

$$\text{RM(observed)} = \text{RM(our Galaxy)} + \text{RM(extragalactic)} \quad (1)$$

$$\text{RM(extragalactic)} = \text{RM(intergalactic)} + \frac{\text{RM(source)}}{(1+z_s)^2} \quad (2)$$

Values of RM(observed) and RM(extragalactic) will be reported elsewhere by myself and P P Kronberg There are two possible ways in which a uniform component of an assumed intergalactic magnetic field can make a contribution to the extragalactic RM of a distant radio source

If the smooth intergalactic density of thermal electrons throughout the observable Universe is sufficiently large, then each volume element along the line of sight to the radio source will contribute to the extragalactic RM, weakened by the factor $(1+z)^2$, where z is the redshift of the volume element So if the lines of sight to two QSOs at different redshifts are very close to each other, they will have a different amount of their extragalactic RM coming from the intergalactic magnetic field

If the intergalactic electron density close to a radio source is much larger than the smooth component permeating the observable universe, then the intergalactic magnetic field close to each radio source will contribute a part to RM, but weakened by the factor $(1+z_s)^2$, where z_s is the radio source redshift

A significant contribution from a random intergalactic magnetic field would contradict the evidence of the least depolarisation occurring with the largest linear and angular sizes of radio sources, as shown by Strom[1,2]

The uniform model

Such a contribution to the extragalactic RM coming from any homogeneous component of an intergalactic magnetic field in a uniform model of the universe is given by

$$\text{RM (intergalactic)} = \int_0^{R_\text{source}} A\cos\theta n_e(R)B(R)(1+z)^{-2}\mathrm{d}R \quad (3)$$

where $A = 8 \ 1 \times 10^5$ rad m^{-2} cm^3 gauss^{-1} pc^{-1}, n_e = electron density (cm^{-3}), B = magnetic field (gauss), θ = angle between direction of B and line of sight, z = redshift of volume element at R, and $\mathrm{d}R$ = element of path length for the radiation coming from the source

From the field equations[3] for zero-pressure models and

$$\Lambda{=}0, \quad \mathrm{d}R = -c\mathrm{d}t = cH_0^{-1} \ \mathrm{d}z(1+z)^{-2}(1+2q_0z)^{-\frac{1}{2}} \quad (4)$$

where c = speed of light, H_0 = Hubble constant, t = cosmic time, and $q_0 =$ deceleration parameter of the Universe

In a homogeneous universe, it is plausible to use the assumptions that

mean matter density $\rho \sim (1+z)^3$
mean electron density $n_e \sim \rho \sim (1+z)^3$
magnetic field $B \sim \rho^{2/3} \sim (1+z)^2$ "frozen-in"

Integrating equation (3)

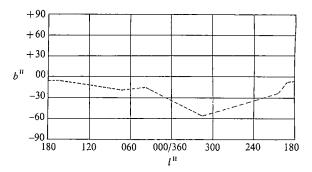
$$\text{RM (intergalactic)} = K\cos\theta F(q_0, z_s) \quad (5)$$

where $\quad K = An_{e_0}B_0(c/H_0)$

and

$$F(q_0z) = [(1+2q_0z)^{3/2} + (6q_0-3)(1+2q_0z)^{1/2} + (2-6q_0)]/6q_0^2$$

and the subscript zero refers to the present epoch An estimate of the numerical value of the quantity K is about 5 rad m^{-2} (assuming $n_{e_0} = 10^{-6}$ cm^{-3}, $B_0 = 10^{-9}$ gauss, $H_0 = 50$ km s^{-1} Mpc^{-1}) The function $F(q_0,z)$ is plotted in Fig 1 for $0 \leqslant z \leqslant 4$, and for q_0 values of 0, 1/2, 1, 2, 3 and 10 $F(q_0,z)$ varies between 0 and 12 for radio sources in this range (A mean density of the Universe of 3×10^{-30} g cm^{-3} corresponds to $n_e \sim 2 \times 10^{-6}$ cm^{-3}, assuming 100% ionisation and 100% hydrogen)

I have used a numerical technique to fit the equation


$$\text{RM (extragalactic)} = KK\,F(q_0,z) + A(3) \pm A(4)/(1+z)^2 \quad (6a)$$

to the data where $KK = K\cos\theta = A(1)$ (rad m^{-2}) and $q_0 = A(2)$ $A(3)$ is a constant residual galactic contribution (rad m^{-2}) and $A(4)$ is the average positive source RM (rad m^{-2}) Because of the smoother magnetic field below the galactic plane[4] I used as input data the extragalactic RMs of 44 QSOs and galaxies with known redshift in approximately half of the South Galactic Hemisphere, as will be discussed elsewhere (J P V and P P Kronberg, unpublished)

This chosen region (Fig 2) lies between the dashed line and the South Galactic Pole It was arrived at by fitting a slab model to represent the galactic magnetic field contribution to the observed RM of discrete radio sources In so doing, the RM with large absolute values (>150 rad m^{-2}) were removed, because of their effect on the least squares fitting technique used We also selected sources with a redshift greater than 0 054 to eliminate unidentified galactic sources as well as to take advantage of the Doppler effect on source RM, enabling the galactic (local) contribution to RM to become more significant The best fitted slab is not necessarily parallel to the galactic plane, and sources not seen through the slab were not used to determine the slab parameters The boundary defining the input sources actually used in the best fitted slab corresponds to the dashed line in Fig 2, enclosing the South Galactic Pole

For all galaxies and known QSOs below the dashed line with observed RM, the galactic contribution to RM was computed and removed First, assuming that cos θ = constant for the redshifted sources below the dashed line, it was found that q_0 varied significantly when using different selection criteria on the input data

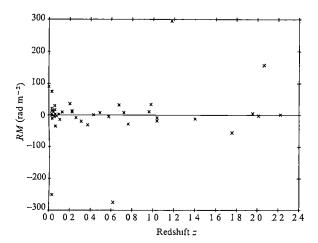
Fig 2 Projection of the sky in galactic coordinates, in which the region of the South Galactic Hemisphere studied in the two models discussed in the text is shown below the dashed line


Fig 3 Plot of the extragalactic rotation measures as a function of the redshift *z* for the 44 QSOs and galaxies studied in the two models

So the approximation $\cos\theta$ = constant was rejected and θ computed for each radio source (assuming a given direction in the sky for the intergalactic magnetic field—see below) with as input data the extragalactic RM divided by $\cos\theta$ The fitting function used was

$$RM \text{ (extragalactic) } /\cos\theta = KF(q_0,z) \qquad (6b)$$

where K and q_0 are to be fitted to the input data

Many trials were made, using three different directions for the assumed intergalactic magnetic field Only a direction towards the spiral arm magnetic field ($l^{II} = 90°$) gave results that were not changed significantly when different selection criteria for the input data were used This can perhaps be explained by a small residual contribution (or overcorrection) from the magnetic field in the galactic spiral arm

As Fig 3 shows, the sample contains about an equal number of sources with positive and negative values of extragalactic RM If there is a sufficiently large contribution from the intergalactic region, then the quantity on the left hand side of equation (6b) should be of the same sign for all the radio sources (except for strong source RM) A plot of this quantity as a function of redshift also shows, however, about an equal number of sources with positive and negative values

So an increase of extragalactic RM with increasing redshift seems ruled out within the errors permitted by the data A useful upper limit to the extragalactic RM from the uniform model would be about 10 rad m^{-2} (Fig 3) This value can be halved if a small residual galactic contribution is accepted ($A(3)$ in equation (6a)) A plausible alternative to the uniform model would be to say that any real contribution from an intergalactic magnetic field would originate near the radio source, instead of in a region far away from a radio source where the mean matter density and the ionisation rate are both likely to be smaller This is the clumpy model

The existence of intergalactic material in clusters of galaxies has often been proposed De Vaucouleurs *et al*[5] presented evidence for intergalactic extinction in the light of normal optical galaxies located close to the plane of the supergalaxy (centred on the Virgo cluster of galaxies) Miley *et al*[6] proposed that the "head-tail" radio galaxies represent the radio trails of the trajectories of active radio galaxies through a dense intergalactic medium within clusters of galaxies In trying to evaluate the contribution to the source rotation measure coming from an ionised intergalactic plasma, a major problem arises because the geometrical distribution of this plasma and the actual position of the radio source in the cluster are not known *a priori*

To facilitate the computations I shall make several assumptions First, the existence of a uniform component of an

intergalactic field Second, that the ionised intergalactic plasma, within several megaparsecs of a radio source, is denser than the possibly smooth component permeating clusters of galaxies or even the Universe Third, a geometrical distribution originating in the following form

Let a radio source at redshift z_s eject n_e electrons cm^{-3} up to a source distance $\Delta R/2$ perpendicular to the intergalactic magnetic field B (no limit in the direction parallel to B) A subsequent diffusion along the lines of B may occur to equalise n_e in this cylindrical model with the radio source on the axis

Provided that the products of n_e,B, and ΔR are within an order of magnitude for most of the radio sources studied, and that the overall angular area in the sky is sufficiently small, the slab model (see above) can test for the existence of the ordered component of an intergalactic magnetic field The input data consist of the extragalactic RM transferred into the source frames by

$$RM \text{(extragalactic)} = \frac{RM\text{(source)} + RM\text{(intergalactic)}}{(1+z_s)^2} \qquad (6c)$$

The same radio sources used in the uniform model were used for analysis of the clumpy model, RM(source)+RM(intergalactic) are listed in Table 1

The best results occur when radio sources with known redshifts are separated according to redshift QSOs at $z > 0.5$ and with RM(source) less than 150 rad m^{-2} yield a direction for a possible magnetic field that is almost parallel (within the errors) to the spiral arm magnetic field in the Southern Galactic Hemisphere It is possible that not all the galactic contribution had been removed from the observed RM because of the idealised

model of a slab, this effect showing up at large z because of the Doppler shift affecting RM(source) Thus, for QSOs at intermediate and large z, the residual galactic contribution is as big or bigger than the extragalactic RM

For radio sources at redshifts closer than 0 5 and with RM (source) less than 150 rad m^{-2}, QSOs and galaxies taken together or separately yield the best results for a magnetic field direction $l^{II} = 200°$, $b^{II} = 0°$, with an error of 40° in both coordinates The parameter K is about -7 rad m^{-2} If we assume an intergalactic electron density n_e close to a radio source in the range 10^{-4} to 10^{-5} cm^{-3}, and a value for ΔR in the range 10^6 to 10^8 pcs, we find that this value for K corresponds to a field strength in the range 10^{-6} to 10^{-9} gauss This is to be compared with the upper limit of about 10^{-7} gauss set by Zel'dovich[7] on the basis of an isotropic cosmological model concerning nuclear reactions But in view of the strong assumptions used in the clumpy model, one cannot state that this last result constitutes a proof for the existence of an intergalactic magnetic field

The intrinsic position angle of linear radiation is determined by the orientation of the magnetic field inside a radio source It is altered neither by the intervening medium between the radio source and the Earth, nor by the Doppler effect Some theoretical models of radio galaxies and QSOs (see ref 8) presuppose the existence of an intergalactic magnetic field in the region of space where a radio galaxy or a QSO occurs These models have the rotational axis of a galaxy orthogonal to the direction of the intergalactic magnetic field Magnetic

"tongues" erupt along the rotational axis, and radio emission commences with the ejection of relativistic electrons into the tongues, through the synchroton process, it is polarised with the electric vector parallel to the direction of the intergalactic magnetic field (for young radio sources) According to Piddington's model[8] neighbouring sources may therefore have similar E–vector orientations

I have plotted the 114 redshifted QSOs and galaxies with known RM in the Southern Galactic Hemisphere[9] on Mercator maps, each radio source in its proper redshift range The redshift ranges were $0 < z < 0 1$, $0 1 < z < 0 2$, $0 2 < z < 0 3$, $0 3 < z < 0 5$, $0 5 < z < 0 7$, $0 7 < z < 1 0$, $1 0 < z < 1 5$, $1 5 < z < 2 3$ The median number of sources on these plots was nine A qualitative study of the intrinsic position angles shown on these plots in various redshift ranges failed to indicate any parallelism, even for neighbouring sources in the sky

I thank Drs P P Kronberg and J F C Wardle for providing data in advance of publication Financial support has been provided by the National Research Council of Canada

A gene cluster in *Aspergillus nidulans* with an internally located *cis*-acting regulatory region

Herbert N. Arst Jr & Donald W. MacDonald

Department of Genetics, University of Cambridge, Milton Road, Cambridge CB4 1XH, UK

Work reported here on the fungus Aspergillus nidulans *has provided the first definitive demonstration of operon-type organisation in an eukaryote genome It has been shown that the* prnA *and* prnB *genes concerned with proline metabolism form a gene cluster with the regulatory region lying between the two putative structural genes* prnA *and* prnB *Regulatory mutations* (prn^d) *probably leading to relief of carbon catabolite repression, map in between* prnA *and* prnB *and are* cis-*dominant with respect to both The properties of these regulatory mutations and other findings suggest that carbon catabolite repression may be mediated by a negative control system in* A nidulans *This gene cluster is particularly interesting in view of its divergent orientation (with the regulatory region located in the centre of the operon) and for the fact that unlike the divergent operons known in prokaryotes, the divergent orientation is related to the way in which this particular operon may be regulated*

IN the ascomycete fungi, one of the most genetically well characterised groups of eukaryotes, clustering of functionally related genes is relatively rare It is generally confined to

instances in which the clustered genes code for enzymes which form aggregates (refs 1 and 2 and D J Cove, H N Arst, and C Scazzocchio, in preparation) None of the few clusters which have been reported has been demonstrated to contain an internal control region such as that described[3,4] in the *arg*ECBH cluster of *Escherichia coli*, where transcription proceeds divergently[5,6] Indeed, there has been no convincing demonstration of a *cis*-acting control region associated with a fungal gene cluster at all

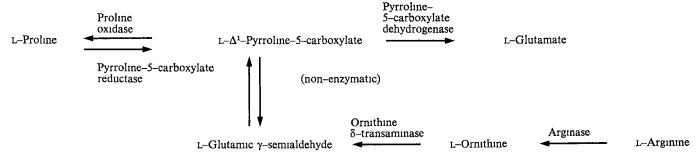
In *Saccharomyces cerevisiae*, however, there are several reports of *cis*-dominant operator constitutive type mutations adjacent to negatively controlled structural genes[7-10] In *Aspergillus nidulans* (D J Cove *et al*, unpublished) and *Neurospora crassa*[1], the preponderance of positive control systems weighs heavily against the probability of obtaining *cis*-acting regulatory mutations Initiator constitutive mutations should be rare and the more frequent initiator negative mutations will be difficult to distinguish from negative mutations in adjacent structural genes under their control New and powerful selective techniques have resulted, however, from an extensive study[11] of nitrogen metabolite repression (ammonium repression of the syntheses of enzymes involved in nitrogen metabolism) in *Aspergillus nidulans* The product of a gene designated *area* is likely to be a positive control element which allows the synthesis of a large number of enzymes and permeases involved in nitrogen metabolism One class of mutations, designated *area^r*, leads to loss of these enzymes and permeases and a


Fig. 1 Pathways of proline, ornithine, and arginine catabolism

consequent inability to utilise a wide variety of nitrogen sources other than ammonium Presumably, *areA*ʳ mutants lack a functional *areA* product Given the pleiotropic nature of the *areA*ʳ phenotype, suppressor mutations affecting the regulation of a single enzyme or a group of enzymes having a common regulatory element can readily be detected For example, mutations which relieve carbon catabolite repression have been obtained because they enable *areA*ʳ strains to utilise those nitrogen sources catabolised by carbon catabolite-repressible enzymes[11,12]

Here we present evidence that the regulation of proline catabolism in *A nidulans* involves three distinct forms of control induction, nitrogen metabolite repression, and carbon catabolite repression

Moreover, a putative structural gene for a proline permease is tightly linked to a putative structural gene for a component common to proline oxidase and Δ^1-pyrroline-5-carboxylate dehydrogenase Between these two genes is a region in which *cis*-acting regulatory mutations affect the expression of both

Control of proline transport and catabolism

The relevant pathways[13-17] of proline and ornithine catabolism are shown in Fig 1 Control characteristics of proline transport,

Fourteen mutants unable to utilise proline as a nitrogen source were isolated after N-methyl-N'-nitro-N-nitrosoguanidine (NTG) mutagenesis[26] of a strain of genotype *yA-2 proA-6 puA-2* (yellow conidial colour, proline-requiring, putrescine-requiring), using the putrescine starvation selection technique[27] On the basis of growth responses (Tables 4 and 5) and complementation tests, eight of these were designated *prnA*⁻ and the other six *prnB*⁻ *prnA*⁻ and *prnB*⁻ mutations are recessive and complement with each other in heterokaryons and diploids Most further work has been done with *prnA-1* and *prnB-6* The tight linkage of *prn*ᵈ mutations to *prnA* and *prnB* makes it impracticable to obtain *prn*ᵈ *prnA*⁻ and *prn*ᵈ *prnB*⁻ double mutants by recombination Therefore, *prnA-33*, *prnB-32*, *prnB-35*, and *prnB-36* were selected after NTG mutagenesis of a *yA-2 proA-6 puA-2 prn*ᵈ-20 strain and *prnB-50* was selected after NTG mutagenesis of a strain of genotype *proA-6 puA-2 prn*ᵈ-21 *fwA-1* (*fwA-1* leading to fawn conidial colour) using the method outlined above All of these *prnA*⁻ and *prnB*⁻ mutations are recessive and their locus designations have been confirmed by diploid complementation tests Retention of the *prn*ᵈ mutation has been demonstrated in every case by its recovery on outcrossing

For uptake studies, outcrossed strains carrying *pabaA-1* (*p*-aminobenzoate requirement) were used The *prn*ᵈ-20 *prnB-36* strain also carries *fwA-1* Otherwise, all strains are isogenic, apart from the specified genotype Mycelia were grown for 21 h at 25 °C in appropriately supplemented shaken liquid minimal medium[28] containing either 0 3 or 1% D-glucose as carbon source and either 595 µM uric acid or 10 mM NH₄⁺ (as the (+)-tartrate) as nitrogen source The medium was buffered to pH 6 5 using 10 mmol l⁻¹ orthophosphate (as the sodium salts) Where the medium was made 5 mM with respect to L-proline, this was done after 16 h growth Mycelia were collected by filtration on to nylon mesh washed with sterile, proline-free medium at 25 °C, and resuspended in the appropriate fresh sterile growth medium without proline Aliquots (1 0 ml) of this suspension were transferred to 50 ml Erlenmeyer flasks containing 9 0 ml of the respective growth media without proline L-proline-U-¹⁴C was added to each flask so as to give a final concentration of 200 µM at a specific activity of 125 mCi mol⁻¹ Flasks were incubated at 25 °C in an orbital shaker Duplicate 5 0 ml samples were taken after 0 and 5 min incubation Each sample was filtered on to a preweighed 2 5 cm diameter Whatman GF/A filter paper, washed with 10 ml ice-cold 200 µM L-proline (unlabelled) followed by 10 ml ice-cold distilled water The filters were dried for 3 h at 90 °C, weighed again, placed in 10 ml of toluene scintillant containing 4 0 g 2,5-diphenyloxazole and 40 mg 1,4-bis-(2-(5-phenyloxazoyl))-benzene l⁻¹, and counted in a Packard 3375 Tri-Carb Scintillation Counter Uptake of L-proline was linear up to 20-30 min incubation and was completely inhibited by 5 mM KCN or 100 µg ml⁻¹ 2,4-dinitrophenol Zero time values have been subtracted from 5 min values to correct for nonspecific adsorption Results are expressed in nmol L-proline per min per mg dry weight Corrected values have been obtained by subtracting the activities present in the *prnB-6* strain under each set of growth conditions from the values for the strain specified in the table This correction eliminates the contribution of the minor proline permease (see below)

In addition to the major proline permease whose control is outlined in this paper, there is at least one minor proline permease It is most clearly observed in mutants lacking the major permease (*prnB*⁻) This minor permease, which is responsible for the leakiness of *prnB*⁻ mutants, does not respond to induction by proline but is markedly inhibited or repressed by ammonium This ammonium inhibition or repression is also apparent from the increased sensitivity of proline oxidase to ammonium repression in *prnB*⁻ strains (Table 2) as a result of inducer exclusion Ammonium inhibition or repression of the minor permease is sufficient to account for the slight effect of ammonium on proline transport in the wild type seen above

0 3% glucose was chosen for transport studies in preference to lower concentrations so as not to restrict the energy available for the uptake process itself, even though carbon catabolite repression is still evident at this concentration A strain carrying *creA*ᵈ-1, which relieves carbon catabolite repression of the syntheses of a number of enzymes[11 12], has been included as it also relieves carbon catabolite repression of proline transport

Table 2 Proline oxidase activities of wild type and mutant strains

Relevant genotype	Relative activities of proline oxidase of mycelia grown in media with 595 µM uric acid as N										
	1% D-glucose as C					0 3% D-glucose as C			0 1% D-glucose as C

prn^d-20 prnA-33	0 0	0 0	0 0	0 0	0 0	—	—	—	—	—	—
prn^d-20 prnB-36	1 7	42	12	62	0 0	16	98	3 0	6 0	81	9 0

All strains carry *paba*A-1, and the *prn*^{d}-20 *prn*B-36 strain also carries *fw*A-1 Otherwise, all strains are isogenic, apart from the specified genotype Mycelia for enzyme assays were grown, collected and extracted as described previously[28,29] in appropriately supplemented shaken liquid minimal medium with D-glucose at the specified concentrations as carbon source and 595 µM uric acid as nitrogen source Mycelia were grown for 21 h at 25 °C and, where indicated, 5 mM L-proline or L-ornithine (as the monohydrochloride) with or without 10 mM NH$_4^+$ (as the (+)-tartrate) was added after 16 h growth Cell-free extracts were prepared in 100 mM Tris-HCl buffer *p*H 7 5 containing 500 mM sucrose The crude homogenates were centrifuged at 12,000*g* for 10 min, and the supernatants taken for enzyme assay

Proline oxidase (EC 1 4 3 2) assays were carried out in 1 cm cuvettes in a double beam spectrophotometer, at 30 °C The assay mixtures contained in a total volume of 3 0 ml 200 µmol Tris-HCl *p*H 8 5, 10 µmol 2-(4-iodophenyl)-3-(4-nitrophenyl)-5-phenyltetrazolium chloride, 1 3 µmol N-methylphenazonium methosulphate, 42 nmol FAD, and 0 1 ml enzyme extract containing 200-500 µg protein The reaction was started by adding 150 µmol L-proline The blank cell contained all components of the assay with the exception of proline and the increase in absorbance at 500 nm was measured Soluble protein in extracts was determined by the Biuret method[30], and results were expressed as a percentage of the specific activity of the wild type when grown on 1 % glucose and induced with 5 mM L-proline

Induction of proline oxidase by ornithine requires its conversion to glutamic γ-semialdehyde (or Δ^1-pyrroline-5-carboxylate) as it does not occur in strains lacking ornithine δ-transaminase whereas proline induction occurs normally (data not shown)

proline oxidase, and Δ^1-pyrroline-5-carboxylate (P5C) dehydrogenase in the wild type can be deduced from Tables 1, 2, and 3, respectively All three activities are inducible Proline transport and proline oxidase at least are carbon catabolite-repressible (carbon catabolite repression of P5C dehydrogenase has not yet been investigated) But, whereas proline oxidase and P5C dehydrogenase are ammonium-repressible, proline transport clearly is not

It should be noted that ammonium represses proline oxidase even when there is little or no carbon catabolite repression (at 0 1% glucose) (Table 2) Thus carbon catabolite repression is probably not a prerequisite for nitrogen metabolite repression where the two forms of control coexist Rather, these data suggest that the two forms of control operate more or less independently of each other

Mutants unable to catabolise proline

Selection of *prn*A⁻ and *prn*B⁻ mutations is described in the legend to Table 1 *prn*A⁻ strains lack both proline oxidase and P5C dehydrogenase (Tables 2 and 3) but are normal for proline transport (Table 1) in agreement with their *in vivo* behaviour (Tables 4 and 5) *prn*B⁻ strains are defective in proline transport (Tables 1 and 5) Consistent with this uptake defect, they show somewhat reduced levels of proline oxidase and P5C dehydrogenase when proline, but not ornithine, is used as inducer (Tables 2 and 3)

Regulatory mutations affecting proline catabolism

*are*A^r and *prn*^{d} mutations have been described previously[11] *prn*^{d} mutations are locus-specific suppressors of *are*A^r mutations, uniquely permitting utilisation of proline as nitrogen source

prn^d-20 does not markedly affect uninduced levels of proline uptake, proline oxidase, or P5C dehydrogenase (Tables 1, 2 and 3) It does, however, result in derepression For proline uptake, which is not ammonium-repressible, *prn*^{d}-20 is probably best interpreted as conferring carbon catabolite derepression This is most clear in the presence of a partially carbon catabolite-repressing glucose concentration such as 0 3% (see

Table 3 Δ^1-Pyrroline-5-carboxylate dehydrogenase activities of wild type and mutant strains

Relevant genotype	Relative activities of P5C dehydrogenase of mycelia grown in media with 1% D-glucose as C+5 mM urea as N			
	−	5 mM L-proline	5 mM L-proline + 10 mM NH$_4^+$	5 mM L-ornithine
Wild type I	2 7	100	25	—
Wild type II	0 0	115	20	25
prnA-1	0 0	0 0	—	—
prnB-6	0 0	76	—	—
prn^d-20	0 0	103	56	—

The wild type I, *prn*A-1, *prn*B-6, and *prn*^{d}-20 strains carry *paba*A-1, and the wild type II strain carries *bi*A-1, a biotin auxotrophy, but is *paba*A$^+$ Otherwise, all strains are isogenic, apart from the specified genotype Experimental details are given in the legend to Table 2 with the following modifications and additions Cell-free extracts were prepared in 100 mM Tris-HCl buffer *p*H 7 5 containing 20% (v/v) glycerol Pyrroline-5-carboxylate dehydrogenase (EC number not assigned) assays were carried out in 1 cm cuvettes in a double beam spectrophotometer at 25 °C The assay mixtures, modified after Strecker[31], contained in a total volume of 3 0 ml 250 µmol Tris-HCl *p*H 8 5, 3 0 µmol NAD, and 0 1 ml of enzyme extract The reaction was started by adding 6 µmol DL-Δ^1-pyrroline-5-carboxylic acid, synthesised as described by Strecker[32] The blank cell contained all components except pyrroline-5-carboxylate, and the increase in absorbance was measured at 340 nm Results are expressed as a percentage of the specific activity of wild type I (*paba*A-1) when grown on 1 % glucose and 5 mM urea and induced with 5 mM L-proline

legend to Table 1) From the enzyme data is it not possible to deduce whether derepression of prn^d-20 is the consequence of carbon catabolite derepression or ammonium derepression or both since the relative contributions of the two forms of repression cannot be clearly distinguished (see ref 11) But, by analogy with the permease results, we favour a model in which prn^d-20 relieves carbon catabolite repression of the proline catabolic enzymes Mutations relieving carbon catabolite repression of the enzymes of proline degradation have been reported in *Salmonella typhimurium*[18]

Epistasis relationships

prn^d mutations do not suppress $prnA^-$ or $prnB^-$ mutations (Tables 1, 2, 4, and 5) Therefore prn^d mutations affect the regulation of the proline oxidase and the P5C dehydrogenase which are missing in $prnA^-$ strains and of the proline transport system which is missing in $prnB^-$ strains

both the $prnA$ and $prnB$ genes Diploids of the following (relevant) genotypes were constructed

$$\frac{areA^r\text{-}1\ prn^d\text{-}20\ prnA\text{-}33}{areA^r\text{-}1\ \ +\ \ } \qquad \frac{areA^r\text{-}1\ prn^d\text{-}20\ prnB\text{-}32,}{areA^r\text{-}1\ \ +\ \ }$$

$$\frac{areA^r\text{-}1\ prn^d\text{-}20\ prnB\text{-}35}{areA^r\text{-}1\ \ +\ \ } \qquad \frac{areA^r\text{-}1\ prn^d\text{-}20\ prnB\text{-}36}{areA^r\text{-}1\ \ +\ \ }$$

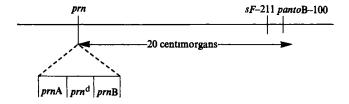
All are unable to utilise proline as nitrogen source (The presence of prn^d-20 in $areA^r$-1 prn^d-20 $prnA$(or B)$^-$ strains was verified by crossing to an $areA^r$-1 strain and recovering progeny able to grow on proline as nitrogen source (genotype of progeny $areA^r$-1prn^d-20)) Diploids of (relevant) genotype ($areA^r$-1 prn^d-20 +)/($areA^r$-1 + $prnA$-1) and ($areA^r$-1 prn^d-20 +)/($areA^r$-1 + $prnB$-6) utilise proline as well as ($areA^r$-1 prn^d-20)/($areA^r$-1 +) diploids

Table 4 Growth responses of wild type and mutant strains

Relevant genotype	Growth on media containing					
	1% D-glucose as C+ as N at 5 mM			10 mM NH$_4$Cl as N as C+ at 50 mM		
	L-proline	L-ornithine	L-glutamate	L-proline	L-ornithine	L-glutamate
Wild type	++	++	++	+	+	+
$prnA^-$	−	±	++	−	−	+
$prnB^-$	±	++	++	±	+	+
prn^d	++	++	++	+	+	+
$otaA^-$	++	−	++	+	−	+
$areA^r$	−	−	−	+	+	+
$prnA^-\ prnB^-$	−	±	++	−	−	+
$prn^d\ prnA^-$	−	±	++	−	−	+
$prn^d\ prnB^-$	±	++	++	±	+	+
$areA^r\ prn^d$	+	−	−	+	+	+
$prnA^-\ otaA^-$	−	−	++	−	−	+
$areA^r\ prn^d\ prnA^-$	−	−	−	−	−	+
$areA^r\ prn^d\ prnB^-$	−	−	−	±	+	+

Growth tests were carried out at 37 °C on appropriately supplemented solid minimum medium[28] L-ornithine was added as the monohydrochloride, and L-glutamate was added as the monosodium salt The $otaA^-$ allele used here was $otaA$-2, selected as resulting in reduced utilisation of arginine as nitrogen source (L M Palmer and H N Arst, unpublished) It is phenotypically identical to its allele $otaA$-1, leading to loss of ornithine δ-transaminase, selected as preventing endogenously channelled or exogenously supplied arginine and ornithine from supplementing proline auxotrophies resulting from blocks between L-glutamate and L-glutamic γ-semialdehyde (Δ^1-pyrroline-5-carboxylate) in the proline biosynthetic pathway[13,14] The alternative pathway of proline biosynthesis from arginine and ornithine is shown in Fig 1 Gene symbols other than $otaA$ are introduced in the text

One noteworthy relationship is the lack of epistasis of $areA^r$ mutations to $prnB^-$ mutations with respect to supplementation of proline auxotrophies (Table 5) When ammonium is present to repress or inhibit the residual proline uptake present in $prnB^-$ strains (legend to Table 1), $prnB^-$ mutations prevent supplementation of proline auxotrophies by limiting levels of proline $areA^r$ mutations do not have this effect $proA^-\ areA^r$ $prnB^-$ triply mutant strains show an intermediate growth response between that of $proA^-$ (or $proA^-\ areA^r$) and $proA^-$ $prnB^-$ strains (Table 5) This is unlikely to be an allele-specific phenomenon because it occurs with $areA^r$-1, $areA^r$-2, and $areA^r$-19 (formerly designated $amdT$-19[11,19]) Therefore the $areA^r$ phenotype does not include loss of the $prnB$ function under conditions in which it completely abolishes utilisation of proline as a nitrogen source Thus, the lack of ammonium repression of the $prnB$ permease is confirmed *in vivo* by differences in $areA^r$ and $prnB^-$ phenotypes and the lack of epistasis of $areA^r$ to $prnB^-$

Cis-dominance of prn^d-20


Diploids of (relevant) genotype ($areA^r$-1 prn^d-20)/($areA^r$-1 +) utilise proline as a nitrogen source to an extent which is clearly intermediate between $areA^r$-1 prn^d-20 haploids and $areA^r$-1 prn^+ haploids Cis-trans tests show that the semi-dominance of prn^d-20 reflects the fact that it acts only in cis with respect to

Map positions

Haploidisation analysis[20] located both $prnA$-1 and $prnB$-6 to linkage group VII Meiotic analysis showed them to be tightly linked (2–3 centimorgans) Preliminary work also showed that they are tightly linked to prn^d-20 Therefore crosses containing the following marker configurations were analysed prn^d-20 $prnB$-32 × $prnA$-1, prn^d-20 $prnB$-35 × $prnA$-1, prn^d-20 $prnB$-36 × $prnA$-1, prn^d-20 $prnA$-33 × $prnB$-6, prn^d-21 $prnB$-50 × $prnA$-1 Proline-utilising progeny were isolated and tested for the prn^d phenotype prn^d mutations can be scored in $areA^+$ strains by methods described previously[11] In every case, proline-utilising progeny fell into both prn^d and prn^+ classes For example, among 64 proline-utilising progeny from a cross of configuration prn^d-20 $prnB$-35 × $prnA$-1, there were 27 prn^d-20 and 37 wild type strains Insufficient numbers of progeny were analysed to warrant detailed presentation of quantitative results, but the qualitative results are unequivocal prn^d-20 and -21 map between $prnA^-$ and $prnB^-$ mutations and do not lie markedly closer to one than to the other

As the above crosses were also heterozygous for $pantoB$-100 (pantothenic acid auxotrophy), which maps about 20 centimorgans away, they showed that $pantoB$-100 is located on the $prnB$ side of the prn cluster To orientate the prn cluster on the linkage group VII map, its position with respect to sF-211 (a block beyond sulphite on the sulphate assimilation pathway[21]), closely linked to $pantoB$-100 (ref 22), was deter-

mined by screening for *prn*A-1 among *s*F⁺ *panto*B⁺ progeny of a cross of marker configuration *s*F-211 × *panto*B-100 *prn*A-1 The linkage data can be summarised as follows

*ota*A-2 (ornithine δ-transaminaseless[13]) is also in linkage group VII (L M Palmer, unpublished), but it recombines freely with mutations in the *prn* cluster

*prn*ᵈ Mutations are not allelic to *prn*A— or *prn*B— mutations

There is compelling evidence that *prn*ᵈ mutations cannot be allelic either to *prn*A⁻ or to *prn*B⁻ mutations Firstly, *prn*ᵈ mutations affect both proline uptake and the enzymes proline oxidase and P5C dehydrogenase (Tables 1, 2 and 3) *prn*A⁻ mutations do not affect proline uptake *prn*B⁻ mutations do not affect the levels of the two enzymes (except to an extent which is attributable to reduced inducer uptake when proline is used to induce)

Second, since *prn*ᵈ mutations lack *trans* activity, they do not alter the structure of a diffusible product Since *prn*A⁻ and *prn*B⁻ mutations complement each other, these mutations do alter the structure of diffusible products Given that *cis*-acting regulatory regions are unlikely to overlap with structural genes, *prn*ᵈ mutations cannot be allelic to either *prn*A⁻ or *prn*B⁻ mutations

Gene regulation

We favour a model in which *prn*ᵈ mutations define a distinct regulatory region located between two structural genes, *prn*A and *prn*B Although it is clear that *prn*ᵈ mutations do not occur in the *prn*A and *prn*B genes, we have not yet attempted to show directly that *prn*ᵈ mutations do not alter the structure of the proline permease, proline oxidase, or P5C dehydrogenase Unfortunately, preliminary attempts to obtain conditional *prn*A⁻ and *prn*B⁻ mutations, which might allow definitive identification of structural genes, have been unsuccessful (D J Cove and H N Arst, unpublished) There is no evidence that mutations in genes other than *prn*A can lead to loss of proline oxidase, but very recently a mutation whose

in vivo behaviour suggests that it eliminates P5C dehydrogenase has been obtained (H N Arst, unpublished) It has not yet been located

A divergent orientation with an internal control region is an obvious way to organise two clustered genes (or sets of genes) having at least one control element in common and one control element not in common Whereas both the *prn*A and the *prn*B products are probably subject to induction and carbon catabolite repression, only the *prn*A product is likely to be subject to nitrogen metabolite repression As *prn*ᵈ mutations affect the control of both *prn*A and *prn*B but do not significantly affect induction, they would seem to involve principally carbon catabolite derepression Future work will be directed towards elucidating the induction process and, in the case of *prn*A, the mechanism of nitrogen metabolite repression

An intriguing aspect of *prn*ᵈ mutations is the high frequency with which they are induced (H N Arst, unpublished), suggesting that the target in the region between *prn*A and *prn*B where mutation can result in the *prn*ᵈ phenotype is rather large Perhaps *prn*ᵈ mutations occur in a receptor site for a negative control element There are other indications that carbon catabolite repression might be mediated by a negative control mechanism in *A nidulans* *cre*Aᵈ-1, leading to carbon catabolite derepression, is recessive[12], and *cre*Aᵈ mutations are not uncommon (C Bailey and H N Arst, unpublished) The role of the *cre*A gene in carbon catabolite repression has yet to be established, but these observations are consistent with its coding for a repressor which binds to sites such as that where *prn*ᵈ mutations occur Extensive attempts to obtain mutants simultaneously defective in the utilisation of several carbon sources have failed (C Bailey and H N Arst, unpublished), which is consistent with the expected rarity of a super-repressed phenotype Moreover, a negative model for carbon catabolite repression provides a rationale for the observation[11] that, among a number of nitrogen sources on which revertants of *are*Aʳ strains have been obtained, specific suppressor mutations have been selected only for proline and acetamide These are the only two nitrogen sources whose utilisation by *are*Aʳ mutants can be achieved by the alleviation of carbon catabolite repression Obtaining *cis*-acting regulatory mutations adjacent to *amd*S, the structural gene for acetamidase[23], is complicated by the occurrence of mutations in two unlinked regulatory genes, *amd*R[11,24] and *amd*A (H N Arst, unpublished), suppressing *are*Aʳ mutations on acetamide While revising this manuscript, we learned that Hynes[25] obtained a *cis*-dominant regulatory mutation tightly linked to *amd*S He prefers to interpret his mutation as leading to increased inducibility, but his data do not eliminate the possibility that it leads to carbon catabolite derepression

Table 5 Effects of various mutations on supplementation of proline auxotrophies

Relevant genotype	Growth using supplementation by		
	5 mM L-proline	250 μM L-proline	5 mM L-ornithine or L-arginine
*pro*A⁻	++	+	++
*pro*A⁻ *prn*A⁻	++	+	++
*pro*A⁻ *prn*B⁻	++	−	++
*pro*A⁻ *prn*ᵈ	++	+	++
*pro*A⁻ *ota*A⁻	++	+	++
*pro*A⁻ *are*Aʳ	++	+	−
*pro*A⁻ *are*Aʳ *prn*B⁻	++	±	++
*pro*A⁻ *prn*ᵈ *prn*B⁻	++	−	++
*pro*A⁻ *prn*A⁻ *prn*B⁻	++	−	++
*pro*A⁻ *are*Aʳ *prn*ᵈ *prn*B⁻	++	±	++
*pro*B⁻	++	+	++
*pro*B⁻ *prn*B⁻	++	−	++
*pro*B⁻ *ota*A⁻	++	+	−

Growth tests were carried out at 37 °C on appropriately supplemented solid minimal medium[28] with 1% D-glucose and 10 mm NH₄⁺ (as the (+)-tartrate) as C and N sources, respectively *pro*A-6 and *pro*B-3 were utilised as the *pro*A⁻ and *pro*B⁻ alleles respectively They are closely linked but non allelic mutations to proline auxotrophy and are blocked between L-glutamate and L-glutamic γ-semialdehyde (Δ¹-pyrroline-5-carboxylate) on the proline biosynthetic pathway[14] Gene symbols other than *pro*A and *pro*B are introduced in the text and the legend to Table 4

Note that *pro*A⁻ *are*Aʳ *prn*B⁻ triple mutants respond better to limiting proline levels (250 μM) than *pro*A⁻ *prn*B⁻ double mutants This is probably the result of the lack of an ammonium-repressible ammonium transport system in *are*Aʳ strains[11], assuming that ammonium must enter the cell to inhibit or repress residual proline uptake

Whatever the mechanism of carbon catabolite repression in *A nidulans*, the nature of the effector involved is an open question Neither cyclic AMP nor its N^6-2'-O-dibutyryl derivative seem to reverse carbon catabolite repression in any of several sensitive *in vivo* diagnostic systems (C Bailey and H N Arst, unpublished) But there is no evidence that these compounds actually enter the cell, for they neither supplement adenine auxotrophies nor serve as nitrogen sources

We believe this to be the first definitive demonstration of an operon-type structure (as opposed to simple tight linkage of functionally related genes) in an eukaryotic organism

We thank Roger Crane, Angela Bohan, and David Webb for technical assistance and Claudio Scazzocchio, Dick LePage, Chris Bailey, and David Cove for useful discussions H N A thanks the Science Research Council for support, through a grant to Dr D J Cove

Note added in proof Recessive mutations eliminating P5C dehydrogenase whilst not reducing levels of proline transport or proline oxidase define another gene, *prnC prnC⁻* mutations are tightly linked to the other *prn* mutations, with the map, order being *prnA prnB prnC* *pantoB*

Initiator constitutive mutation with an 'up-promoter' effect in *Aspergillus nidulans*

Herbert N. Arst Jr & Claudio Scazzocchio*

Department of Genetics, University of Cambridge, Milton Road, Cambridge CB4 1XH, UK

A mutation leading to strong constitutivity for a uric acid-xanthine permease in the lower eukaryote Aspergillus nidulans has been found to be tightly linked to the putative structural gene whose expression it controls in the cis configuration In addition, it increases the maximal induced level of transport 2 5-fold This is the first demonstration of an initiator or promoter mutation in an eukaryote

STUDIES on the regulation of enzyme synthesis in the fungus *Aspergillus nidulans* are increasingly uncovering instances in which such synthesis is subject to multiple forms of regulation For example, in the accompanying paper[1], it is shown that the synthesis of enzymes involved in proline degradation is inducible and is also repressible by both carbon catabolite and nitrogen metabolite repression Another example is provided by the *hxB* gene, which codes for a subunit common to two enzymes[2], each of which is subject both to a specific induction system and to nitrogen metabolite repression[3-5] It is reasonable to assume that adjacent to each multiply regulated structural gene there are receptor sites specific for the respective proteins coded by each regulatory gene involved These sites may or may not overlap Evidence for multiple regulatory sites has been reported in the *lac*, *ara*, and, notably, *gal* operons of *Escherichia coli* (refs 6, 7, 8, and references therein)

In *Aspergillus nidulans*, a permease specific for uric acid and xanthine[9] is both inducible and ammonium-repressible Expression of the gene coding for the permease requires the products of two positive control genes the *uaY* gene, necessary for induction (refs 3, 10, and D J Cove, H N Arst, and C

* Present address Department of Biology, University of Essex, Wivenhoe Park, Colchester CO4 3SQ, UK

Scazzocchio, unpublished), and the *areA* gene, necessary for the expression of all genes subject to nitrogen metabolite (ammonium) repression[5] Presumably the structural gene (or its RNA transcript) for the uric acid–xanthine permease is adjacent to two receptor sites, one able to bind the product of the *uaY* gene in the presence of coinducer (uric acid[10]) and another able to bind the product of the *areA* gene in the absence of corepressor (presumably ammonium) As a great number of enzymes and permeases are subject to ammonium repression, regions of (presumably) DNA able to bind the *areA* product should be widely distributed throughout the genome Since activities coded by different genes respond in different ways to almost every allele of the *areA* gene[5], one can only presume that these recognition sites are not all identical Moreover, mutations in the *areA* gene can also affect the maximal level of synthesis of any of these enzymes or permeases[5], suggesting that at least a functional overlap might exist between the receptor site for the *areA* product and a promoter site In the *lac* operon of *E coli*, not only is there at least a functional overlap between the promoter site (for binding RNA polymerase) and the binding site for the catabolite activator protein[11,12], but most operator constitutive mutations show more or less marked promoter effects[13] Recent research in the bacteriophage λ has shown a physical overlap of promoter and operator sites[14,15]

A general method to identify control regions adjacent to structural genes under *areA* control should be to select *cis*-acting mutations which permit the expression of a given structural gene in the presence of a non functional *areA* allele But most *areA* mutations result in loss of many, if not all, of the activities subject to ammonium repression As the genes coding for enzymes catalysing sequential steps in a given pathway are generally not clustered in *Aspergillus*[16], mutations at more than one receptor site would be necessary to

Table 1 *In vivo* responses to xanthine, uric acid, and their analogues

Relevant genotype	Inhibition of hypoxanthine utilisation by allopurinol at		Sensitivity to Inhibition of green pigment formation by 2-thioxanthine or 2-thiouric acid at		Inhibition of growth of strains also carrying an *al*X—mutation by xanthine or uric acid at

uap-100	S	S	S	S	S	S
uap-100 *uap*A⁻	R	R	R	R	R	R

S=Sensitive, R=resistant

Five mutations leading to defective transport of uric acid and xanthine (*uap*A⁻)[9] were obtained, after NTG mutagenesis, in a strain of genotype *paba*A-1, as conferring resistance to 100 μg ml⁻¹ 2-thioxanthine, a xanthine analogue[9], on hypoxanthine as sole nitrogen source The use of hypoxanthine discards all mutants lacking xanthine dehydrogenase[24], leaving *uap*A⁻ mutants as the major class One mutation, *uap*A-24, was used for transport and genetical studies. Because of the tight linkage of *uap*A⁻ mutations to *uap*-100 and the lack of external markers, it was not feasible to obtain *uap*-100 *uap*A⁻ double mutants by recombination Therefore other *uap*A⁻ mutations were selected, using the above method, in a strain carrying *uap*-100 (*uap*-100 *pyro* A-4, auxotrophic for pyridoxine) One mutation, *uap*A-37, was selected for further work and was shown not to complement with *uap*A-24 in diploids *uap*A-24 and *uap*A-37 are both recessive and tightly linked (< 1 centimorgan) to *uap*-100 and are therefore allelic These mutations have been located[25] in linkage group I Growth tests were made on appropriately supplemented solid minimal medium[26] at 37 °C Inhibition by allopurinol was tested using 100 μg ml⁻¹ hypoxanthine as nitrogen source Inhibition by 2-thioxanthine and 2-thiouric acid was tested used 3 3 mH NH₄⁺ as nitrogen source Inhibition by xanthine and uric acid was tested using 10 mM NO₃⁻ as nitrogen source Allopurinol specifically inhibits xanthine dehydrogenase and thus the utilisation of hypoxanthine as nitrogen source[3] 2-thiouric acid inhibits the conversion of yellow to green conidial pigment[9,24,27] 2-thioxanthine is converted by xanthine dehydrogenase to 2-thiouric acid[9,24] Xanthine and uric acid are toxic to strains lacking allantoinase (*al*X⁻) resulting from allantoin accumulation[9] Allopurinol, 2-thiouric acid, 2-thioxanthine, xanthine and uric acid are all substrates of the *uap*A permease[3,9]

obtain a revertant As even single mutations resulting in the ability to bypass the *are*A product or to accommodate a modified *are*A product should be rare, a requirement for multiple mutational events would make the method impracticable

Nevertheless, advantage can be taken of the wide variety of phenotypes displayed by *are*A mutations In particular, one allele, *are*A-102 (formerly designated *amd*T-102), was selected as resulting in derepression of acetamidase[17] But, *are*A-102 also leads to reduced levels of formamidase[17,18] and notably to an almost total lack of transport activity for uric acid and xanthine, whilst not affecting the catabolism of these compounds once inside the cell[5] Thus, a revertant able to grow on uric acid and xanthine as nitrogen sources should result from a single mutational event in a *cis*-acting element controlling the uric acid–xanthine permease This paper describes one such *cis*-dominant mutation, designated *uap*-100, which results in strong constitutivity of the permease as well as a marked 'up-promoter' effect (An 'up-promoter' effect is an increase in the maximal level of expression of the adjacent structural gene) *uap*-100 does not, however, confer derepression *vis-à-vis* ammonium This last characteristic is somewhat surprising in view of the method of selection and will be discussed below

Selection of *uap*-100

uap-100 was obtained after N-methyl-N'-nitro-N-nitrosoguanidine (NTG) mutagenesis[19] of a (*p*-aminobenzoate-requiring) *are*A-102 strain (*paba*A-1 *are*A-102) Conidiospores

were plated on medium containing uric acid as sole nitrogen source, and 42 revertants were isolated Forty-one of these revertants have lost at least one other of the characteristics of the *are*A-102 phenotype and presumably contain second-site reversions in the *are*A gene One revertant has exclusively regained the ability to utilise uric acid and xanthine whilst retaining all other characteristics associated with the *are*A-102 mutation As predicted, it carries a specific suppressor mutation Selection of *uap*A⁻ mutations is described in the legend to Table 1

In vivo properties of *uap*A⁻ and *uap*-100 mutations

Table 1 compares *uap*A⁻, *uap*-100 and wild type strains with regard to sensitivity to a number of purines and purine analogues taken up by way of the *uap*A permease[3,9] Whereas *uap*A⁻ mutations confer resistance to these compounds, *uap*-100 leads to marked hypersensitivity *uap*A⁻ mutations are completely epistatic to *uap*-100

Transport and enzyme studies

2-thiouric acid is a gratuitous inducer of both xanthine dehydrogenase I and urate oxidase in *A nidulans*[20] Tables 2 and 3 show that it also induces a uric acid permease which is missing in strains carrying *uap*A-24 The residual uric acid transport in these strains occurs by means of permeases specified by other genes (H N Arst and C Scazzocchio, unpublished)

Table 2 Induction of uric acid transport activity

Relevant genotype	¹⁴C/³H 2-thiouric acid present in growth medium at (μM)			
	0	2 77	27 7	277
uap⁺	0 0431	0 2763	0 2065	0 1265
uap-100	0 4200	0 6743	0 5403	0 3399

The method for uptake studies has been described in detail previously[28] The ¹⁴C counts monitor uric acid uptake while the ³H counts serve as a measure of protein synthesis and hence growth In addition to the *uap* genotype specified above, both strains carry *y*A-2 (yellow conidial colour), *lu*A-1 (L-leucine auxotrophy), *hx*B-13 (loss of xanthine dehydrogenase), and *ua*Z-11 (loss of urate oxidase) but are otherwise isogenic The use of urate oxidaseless strains allows uptake measurements to be made in the absence of any uric acid catabolism[29] But *ua*Z⁻ strains accumulate uric acid and are therefore pseudo-constitutive for uric acid-induced activities unless they also lack xanthine dehydrogenase[20,30] Hence it is essential to use xanthine dehydrogenaseless strains to study induction Mycelia were grown for 21 h at 37 °C on solid (growth) medium[26] supplemented with 10 μg l⁻¹ biotin, 5 mM urea, 1 mM 4,5-³H-L-leucine at a final specific activity of 500 mCi mol⁻¹, and 2-thiouric acid at the specified concentrations Mycelia were incubated for 30 min at 37 °C in uptake medium supplemented with 10 μg l⁻¹ biotin, 5 mM urea, 1 mM L-leucine (unlabelled), and 59 5 μM 2-¹⁴C-uric acid at a final specific activity of 3 36 Ci mol⁻¹

Table 3 Ammonium repression of uric acid transport activity

Relevant genotype or calculation	None	¹⁴C/³H Additions to growth medium 27 7 µM 2-thiouric acid	10 mM NH₄⁺	27 7 µM 2-thiouric acid +10 mM NH₄⁺
*uap*A-24	0 0201	0 0232	0 0120	0 0162
uap⁺	0 0436	0 2206	0 0470	0 0542
uap-100	0 3931	0 4645	0 0906	0 1165
Activity ratio	15 9	2 3	2 2	2 1

The experimental method was the same as that in the legend to Table 2, except that the additions to the growth medium were those specified above All strains carry *y*A-2, *lu*A-1, *hx*B-13, and *ua*Z-11 (as in Table 2) in addition to the *uap* genotype given above but are otherwise isogenic The activity ratio is calculated as (¹⁴C/³H for *uap*-100 — ¹⁴C/³H for *uap*A-24)/(¹⁴C/³H for *uap*⁺ — ¹⁴C/³H for *uap*A-24) for each set of growth conditions Since the residual uric acid transport activity in *uap*A-24 is probably attributable to permeases other than that specified by the *uap*A gene (H N Arst and C Scazzocchio, unpublished), the activity ratio expresses the ratio of uric acid transport activity by way of the *uap*A permease in the *uap*-100 strain to that in the wild type for any given set of growth conditions

The decline in uptake as higher concentrations of thiouric acid are used to induce probably reflects inhibition of uric acid uptake by preloaded 2-thiouric acid Tables 2 and 3 show that strains carrying *uap*-100 are strongly constitutive for uric acid uptake That the permease responsible for this uptake is the one missing in *uap*A⁻ mutants is shown by the complete epistasis of *uap*A⁻ mutations to *uap*-100 (Table 1) On maximal induction, strains carrying *uap*-100 have 2 5 times the level of uric acid transport found in the induced wild type (Tables 2 and 3) Both induced wild type and induced *uap*-100 show approximately fourfold repressibility by ammonium (Table 3)

Table 4 Induction of urate oxidase by a gratuitous inducer

Concentration of 2-thiouric acid		Urate oxidase specific activity Wild type	*uap*-100
0		<1	<1
27 7	pM	<1	<1
134	pM	3 0	20 9
277	pM	29 3	40 2
2 77	nM	59 5	49 2
27 7	nM	57 6	56 5
277	nM	59 3	50 1

Both strains carry a biotin auxotrophy (*bi*A-1) and are, apart from the specified genotypes, isogenic Mycelium was grown for 20 h at 25 °C in shaken liquid minimal medium[26] supplemented with 10 µg l⁻¹ biotin and containing 5 mM urea 2-thiouric acid was added after 15 h growth Preparation of cell-free extracts and urate oxidase (EC 1 7 3 3) determinations have been described previously[29] Specific activities are defined as nM substrate transformed per min × mg soluble protein Soluble protein in extracts was determined by the Biuret method[31]

Data in Table 4 show that the enhancement of uric acid uptake activity by *uap*-100 is reflected in enhanced sensitivity of urate oxidase induction to 2-thiouric acid The difference is most striking at 134 pM 2-thiouric acid where the *uap*-100 strain is induced to 37% of its maximal level while the wild type is induced to only 5% of its maximal level Comparable

results were also obtained for xanthine dehydrogenase I (data not shown)

Data in Tables 4 and 5 show that uninduced and induced levels of xanthine dehydrogenase I and urate oxidase are not affected by the *uap*-100 mutation These enzymes are, as is the *uap*A permease, under the positive control of the *ua*Y gene (refs 3, 10, and D J Cove, H N Arst and C Scazzocchio, unpublished) Data in Table 5 also show that the apparent degree of ammonium-repressibility of the two enzymes is reduced in *uap*-100 strains when uric acid is used as the inducer As *uap*-100 has no such effect when hypoxanthine is used to induce, part of the apparent ammonium-repressibility can be attributed to inducer exclusion Hypoxanthine, which enters the cell by another permease[9], is able to induce only because it is converted intracellularly to uric acid[20]

Cis-dominance of *uap*-100

Table 6 shows the apparent dominance of *uap*-100 in diploids homozygous for *are*A-102 In this case, the *in vivo* test does not distinguish between semidominance and complete dominance In any event, Table 6 shows clearly that *uap*-100 only affects the expression of a *uap*A gene when located *cis* to it The presence of *uap*-100 in *uap*-100 *uap*aA-37 *are*A-102 strains was verified by crossing to an *are*A-102 strain and recovering progeny able to grow on uric acid as nitrogen source (genotype of progeny *uap*-100 *are*A-102) The presence of *uap*A-37 or *uap*A-24 in strains also carrying *are*A-102 was confirmed by outcrossing to wild type and recovering approximately 25% *uap*A⁻ *are*A⁺ progeny

Nature of the *uap*-100 mutation

We have not yet established that *uap*A is the structural gene for the uric acid–xanthine permease The selection of mutants with altered substrate specificity, now in progress, might provide the necessary proof

Three hypotheses could account for the properties of *uap*-100 (1) The 'up-promoter' effect of *uap*-100 might reflect an altered structure of the permease, increasing the efficiency of uptake The strong constitutivity of *uap*-100 virtually eliminates this

Table 5 Inducer exclusion by ammonium

% Repression with hypoxanthine as inducer	53 1	52 5	95 8	87 6
Uric acid	55 0	41 6	29 8	17 1
Uric acid+ammonium	21 1	27 7	1 5	8 1
% Repression with uric acid as inducer	61 7	33 4	94 1	72 8

Experimental details are given in the legend to Table 4 with the following modifications and additions 50 µg ml⁻¹ hypoxanthine or uric acid with or without 10 mM ammonium (as the (+)-tartrate) was added after 15 h growth Xanthine dehydrogenase I (EC 1 2 1 37) was determined according to Scazzocchio *et al*[3] % Repression=(1-(ammonium-repressed specific activity)/(non-repressed (induced) specific activity))×100

Table 6 *Cis*-dominance of *uap*-100

Relevant genotype			Utilisation of (as nitrogen source)		
			Hypoxanthine	Xanthine	Uric acid
Wild type			−	+	+
*are*A-102			+	−	−
uap-100 *are*A-102			+	+	+
$\dfrac{uap\text{-}100}{+}$ $\dfrac{areA\text{-}102}{areA\text{-}102}$			+	+	+
$\dfrac{uap\text{-}100}{+}$ $\dfrac{uapA\text{-}37}{+}$ $\dfrac{areA\text{-}102}{areA\text{-}102}$			+	−	−
$\dfrac{uap\text{-}100}{+}$ $\dfrac{+}{uapA\text{-}24}$ $\dfrac{areA\text{-}102}{areA\text{-}102}$			+	+	+

Two independent diploids were constructed for both *cis* and *trans* configuration dominance tests Growth tests were carried out at 37 °C on solid minimal medium[26] with purines added at 100 μg ml⁻¹

possibility (2) *uap*-100 is a constitutive allele and *uap*A⁻ mutations are noninducible alleles in a positive control gene This is extremely unlikely as *uap*-100 and *uap*A⁻ mutations do not affect the regulation of the enzymes induced together with the uric acid permease Moreover, the strong 'up-promoter' effect would be unprecedented and difficult to accommodate to this model (3) *uap*-100 is a mutation in a control region adjacent to a structural gene, *uap*A, coding for the uric acid–xanthine permease This hypothesis is consistent with all the data and is definitely the most attractive

Since the *uap*A gene is under the control of two positive regulatory genes, *ua*Y and *are*A, *uap*-100 can be described as an initiator constitutive mutation Work is in progress to establish the nature of the interaction between *uap*-100 and the *ua*Y and *are*A products Preliminary *in vivo* evidence indicates that *uap*-100 partially suppresses *ua*Y⁻ mutations for permeation but does not alleviate the stringent requirement for the *are*A product This latter finding is in essential agreement with the lack of effect of *uap*-100 on the ammonium-repressibility of the *uap*A permease Therefore the suppression of *are*A-102 by *uap*-100 implies that *uap*-100, in contrast to its wild type allele, can accommodate to the modified *are*A product present in *are*A-102 strains Probably the 'up-promoter' effect of *uap*-100 contributes to the magnitude of the suppression 'Up-' and 'down-promoter' effects are a feature of many initiator constitutive mutations in the *ara* (ref 21) and *mal* (ref 22) systems of *E coli*

In addition to the *uap*A permease, *are*A-102 results in the loss of at least one other permease for uric acid and xanthine (H N Arst and C Scazzocchio, unpublished) Although *are*A-102 leads to somewhat reduced levels of a number of enzymes and permeases[5, 17, 18, 23] these two (or more) permeases with overlapping specificities are the only activities which seem to be totally absent in *are*A-102 strains This may be the first direct clue that similarity of binding sites for the *are*A product constitutes a physiologically significant form of control The possibility that *are*A binding sites might exist in discrete classes related to each other by changes involving only a few bases is

suggested by the observation (H N Arst and C Scazzocchio, unpublished) that intracistronic reversions in an *are*A-102 strain yield new *are*A alleles with a phenotype mirroring that of *are*A-102 They result in recovery of uric acid and xanthine uptake activities but in loss of acetamidase

Pairs of *are*A alleles with antisymmetrical properties and their respective initiator specific suppressors could well provide the means to identify and classify initiator sites in an eukaryote by purely genetical means

Determinant of cistron specificity in bacterial ribosomes

J. Shine & L. Dalgarno

Department of Biochemistry, School of General Studies, Australian National University, Canberra ACT 2600, Australia

The sequence of the 3'-terminus of 16S RNA from different bacteria has been determined Complementarity relationships between this sequence and a purine-rich tract in the ribosome binding site of different bacterial mRNAs suggest that the 3'-end of 16S RNA determines the intrinsic capacity of ribosomes to translate a particular cistron

INITIATION of protein synthesis in bacteria involves the specific binding of the small ribosome subunit to a region of the mRNA containing the initiation codon As the initiating 30S subunit discriminates against the many internal AUG or GUG codons and selects only the AUG or GUG triplet at the beginning of a cistron, some feature of the mRNA other than the presence of AUG must be necessary for ribosome recogni-

Table 1 Determination of the 3'-sequence of *C crescentus* 16S RNA

Number of stepwise degradations before labelling with ³H-isoniazid	Radioactivity in nucleoside hydrazones released by pancreatic ribonuclease*				Sequence
	G-iNzd	U-iNzd	A-iNzd	C-iNzd	
0	3 5	83 8	8 1	4 6	PyU_{OH}
1	3 5	8 7	8 0	79 9	$PyCU_{OH}$
2	5 6	74 3	6 4	13 7	$PyUCU_{OH}$
3	8 3	70 4	9 9	11 3	$PyUUCU_{OH}$
4	6 0	71 8	5 1	17 1	$PyUUUCU_{OH}$
5	6 4	19 2	7 3	67 1	$PyCUUUCU_{OH}$
6	7 6	13 3	8 0	71 1	$PyCCUUUCU_{OH}$
7	8 6	62 9	11 4	17 1	$PyUCCUUUCU_{OH}$

C crescentus (ATCC 15252) was grown and collected as described by Leffler and Szer[2] RNA was extracted directly from the cell pellet with a mixture of phenol/cresol-aminosalicylate[35] DNA, low molecular weight RNA and polysaccharide were removed by washing with 3 M sodium acetate[35] 16S RNA was isolated on 5–20% (w/v) sucrose gradients After 3'-terminal labelling, 16S RNA was digested with pancreatic ribonuclease (100 μg per mg RNA) at 20° C for 4 h in 0 01 M Na/K phosphate buffer (*p*H 7 4) A sample of the digest (10 or 20 μl) was mixed with 20 μl of unlabelled mononucleoside hydrazones[39] and electrophoresed on Whatman 3MM paper at 40 V cm⁻¹ for 2 h in 0 1 M sodium formate (*p*H 3)
*Expressed as a percentage of total radioactivity in nucleoside hydrazones separated by paper electrophoresis

tion Such recognition probably involves some as yet undefined component or feature of the untranslated sequence on the 5'-side of the initiator codon After the specific interaction of mRNA with the 30S subunit, stabilisation of the initiation complex is dependent on initiation factors[1-3], and possibly on the 'fractional' ribosomal protein S_1 (ref 4)

Cistron specificity

A number of reports demonstrate that ribosomes from different bacterial species show cistron specificity in the translation of natural mRNAs *in vitro*, irrespective of the source of the initiation factors used[2,5-11] Thus, ribosomes from *Micrococcus cryophilus* or *Pseudomonas* translate protein from all three cistrons of MS2 RNA in the same relative amounts as those from *Escherichia coli*[8] Under comparable conditions *Bacillus stearothermophilus* ribosomes translate only the A-protein cistron of R17 or f2 RNA (refs 5–7) *Caulobacter crescentus* ribosomes are unable to translate any of the MS2 RNA cistrons[2], correspondingly, *E coli* ribosomes do not translate RNA from the *C crescentus* phage Cb5 (ref 2) A similar cistron selectivity is also demonstrated, in the absence of initiation factors, in a weak, but species-specific interaction of ribosomes with certain phage RNAs (ref 4)

Studies with hybrid ribosomes show that the specificity of ribosome binding and translation of natural mRNAs is primarily a function of the 30S subunit[2,7] Two recent reports aimed at determining the component of the 30S subunit responsible, argue that both a ribosomal protein (particularly protein S12) and the 16S RNA determine the specificity of initiation[12,13] The type of recognition process involved, however, is unknown

Base sequence or secondary structure?

The recognition of mRNA initiation signals by 30S subunits could conceivably be determined by a specific base sequence on the 5'-side of the initiation triplet, by the degree or type of secondary structure in this region of the mRNA, or by both factors Ribonuclease digestion of initiation complexes formed on specific mRNAs has made it possible to determine the base sequence of ribosome-binding sites for several mRNA cistrons[6,14-23] Although some of these ribosome-protected sequences probably have a fairly high degree of secondary structure[6,14,19,24], no such secondary structure seems possible for other initiation sites[23,25,26] It therefore seems unlikely that the 30S subunit specifically recognises some feature of the secondary structure of the ribosome-binding site sequence, particularly since a reduction in structure on partial denaturation of intact mRNAs generally increases, rather than decreases, the number of available initiating sites[27,28] This observation therefore suggests that the specific binding of

ribosomes to mRNA may depend on the ribosome-binding site being in an open, single-stranded form, rather than in a structured conformation

It is significant therefore that all coliphage RNA ribosome-binding sites examined to date contain all or part of the purine-rich sequence 5'-AGGAGGU-3' in a similar relative position on the 5'-side of the initiator triplet AUG The ribosome binding site of an endogenous *E coli* mRNA also contains part of this sequence, AGGA (ref 23) We have previously shown that the 3'-terminus of *E coli* 16S RNA contains the sequence 5'-ACCUCCU-3' which is the complement of AGGAGGU (ref 29) This, together with evidence that an intact 3'-terminus of 16S RNA is necessary for protein synthesis in bacteria[30-32] and more recent data suggesting a specific role for the 3'-terminus in initiation[33], have prompted us to suggest that the 3'-terminal sequence of 16S RNA may have a direct base-pairing role in the initiation of protein synthesis on natural mRNAs (ref 29)

This hypothesis predicts that there will be a positive correlation between the translation of a particular bacterial mRNA cistron by bacterial ribosomes, and the degree of complementarity which exists between the ribosome binding site sequence of that cistron and the 3'-terminal sequence of the 16S ribosomal RNA We have therefore determined the 3'-terminal sequences of 16S RNA from *P aeruginosa*, *B stearothermophilus* and *C crescentus* since information exists on both the capacity of ribosomes from these bacteria to translate various bacterial mRNA cistrons, and on the ribosome binding site sequences of the cistrons concerned

3'-terminal sequences

A procedure for the stepwise removal of seven to eight nucleotides from the 3'-terminus was applied to 16S RNA isolated from bacteria (see Tables 1 and 2) This is a cyclic process and involved removal of the periodate-oxidised 3'-nucleoside by incubation in 0 33 M aniline, digestion with alkaline phosphatase to release the 3'-phosphate and periodate-oxidation of the resultant 2',3'-hydroxyl groups[29,34] After removal of successive 3'-nucleosides, the RNA was labelled by condensation with ³H-isoniazid[35] and digested with specific nucleases The labelled 3'-terminus was characterised by chromatography of the ribonuclease digest on DEAE-Sephadex and identification of any 3'-nucleoside hydrazones by paper electrophoresis[36,37]

An outline of the sequence determination for *C crescentus* 16S RNA is shown in Table 1 The 3'-sequences of 16S RNA from the other bacteria, determined by the same method, are listed in Table 2 A general feature of all the 3'-termini is the high proportion of pyrimidine residues Apart from the terminal adenosine, the seven terminal nucleotides at least, are invariably uridylic acid or cytidylic acid

Complementarity to coliphage ribosome-binding site sequences

We have previously shown that the 3'-terminal nucleotides of *E coli* 16S RNA could form seven, four and three base pairs with the appropriate region of the R17 A-protein, replicase and coat-protein ribosome-binding sites, respectively (see Table 3 and ref 29) The extent of this pairing relates closely to the ribosome-binding capacities of the three isolated initiator regions of R17 RNA since *E coli* ribosomes discriminate in favour of the A-protein initiator fragment some fortyfold and elevenfold over the coat and replicase sites, respectively[38] This is in contrast to initiation of the three cistrons on intact R17 RNA where some 20 moles of coat protein and 5 moles of replicase are synthesised for each mole of A-protein[44] Under these conditions the secondary structure of the intact phage RNA presumably impedes binding of the 30S subunit to the A-protein and replicase initiator regions[38]

The 3'-end of *Ps aeruginosa* 16S RNA is identical to that of *E coli* for seven nucleotides, it can be aligned such that five, four and three to four base pairs are possible with the ribosome-binding site sequences of the A-protein, replicase and coat-protein cistrons of R17 RNA, respectively (Table 3) It has been previously shown[8] that *Pseudomonas* ribosomes translate all three cistrons of MS2 RNA in a manner analogous to that of *E coli* ribosomes

B stearothermophilus (and *B subtilis*) 16S RNA has a 3'-sequence significantly different to that of *E coli* and *Ps aeruginosa* 16S RNA (Table 2) Some complementarity ($\geqslant$ four base pairs) exists, however, between this sequence and the ribosome-binding sites of both the A-protein and replicase cistrons of R17 RNA (Table 3) The degree of complementarity possible with the coat-protein binding site is considerably less (one to two base pairs) *B stearothermophilus* ribosomes bind significantly only to the A-protein site on native f2 or R17 RNA (refs 6 and 7) Appreciable translation by *B stearothermophilus* ribosomes of both the replicase and A-protein cistrons does occur, however, after unfolding of the RNA with formaldehyde[28], under these conditions no coat protein is synthesised *B stearothermophilus* ribosomes also exhibit a relatively high level of recognition of the R17 replicase initiation site when assayed at 49 °C (ref 13), the T_m of the short helix containing the R17 replicase initiator region is 48 °C in 0 05 M Na⁺ (ref 24) *B stearothermophilus* ribosomes are therefore intrinsically able to recognise the A-protein and replicase sites but not the coat-protein site, as would be predicted if a minimum of three to four base pairs were necessary to permit stable interaction Presumably the conformation of the native, intact phage RNA usually renders the replicase site inaccessible to *B stearothermophilus* ribosomes

B stearothermophilus ribosomes bind to only a single site on Qβ RNA at 65 °C, which does not correspond to any of the three normal initiator regions[26] The ribonuclease-protected fragment is similar in size to that bound by ribosomes during productive initiation on the A-protein cistron of R17 RNA It contains no initiation triplet, showing that mRNA can be specifically recognised and bound by ribosomes independently of polypeptide chain initiation[26] The fragment, however, contains a polypurine tract of composition G(AAAG,AG,G,G, G)A in a similar relative position to that of AGGAGGU in the R17 A-protein site[26] It is significant therefore that the complement of the 3'-terminus of *B stearothermophilus* 16S RNA is AGAAAGGA

As the 3'-sequence of *C crescentus* 16S RNA is similar to that of *B stearothermophilus* 16S RNA (Table 2), one could predict a similar recognition by *C crescentus* ribosomes of both the A-protein and replicase cistrons of R17 RNA (Table 3) This prediction is not inconsistent with the observed failure of *Caulobacter* ribosomes to translate MS2 RNA at 37 °C, as under these conditions the initiation sites for the A-protein and replicase cistrons are presumably largely masked by the secondary structure of the phage RNA (refs 24 and 38) This is analogous to the very low level of translation of f2 RNA by *B stearothermophilus* ribosomes at 37 °C compared to that found at 65 °C or after mild denaturation of the RNA with formaldehyde[28] It is significant that considerable translation of formaldehyde-treated MS2 RNA occurs with *Caulobacter* ribosomes[2], although the identity of the translated cistrons is not known

The degree of possible interaction between the 3'-terminus of 16S RNA from several different bacteria and the ribosome-binding sites of coliphage RNA is therefore consistent with the available data on translational specificity in these bacteria Confirmation of the hypothesis that the 3'-end of 16S RNA is directly involved in the selection of initiation regions on mRNA must await the sequencing of ribosome-binding sites from other bacterial messengers and direct demonstration of such an interaction For instance, we would predict that the sequences of the ribosome-binding sites from RNA of the *C crescentus* phage Cb5 would contain some part of the sequence complementary to the 3'-end of *C crescentus* 16S RNA, that is, some part of AGAAAGGA

Initiation factors

The role of initiation factors (for example, IF-3) in determining the efficiency of initiation on certain cistrons or mRNAs seems to be related to their capacity to stabilise the mRNA-30S subunit complex[1-3] 30S subunits, possibly through the 3'-end of 16S RNA and protein S12 (ref 12), have an inherent capacity to bind weakly but specifically to mRNA (ref 4) and are stabilised in this interaction by various initiation factors, particularly IF-3 (refs 1-3) and the ribosomal protein S₁ (ref 4)

The role of IF-3, which interacts with both 30S subunits and with mRNA (refs 1-3, 45), could be to potentiate or stabilise base pairing between the 3'-terminus of 16S RNA and the complementary region of the ribosome-binding site Purified IF-3 species promote differential translation of coliphage RNA cistrons[46-48], this may reflect a greater effect of IF-3 in the stabilisation of the mRNA-30S subunit complex at particular initiation sites Thus initiation of the coat-protein cistron of R17 RNA, where only three to four base pairs can be formed between mRNA and the 3'-end of *E coli* 16S RNA, may be highly dependent on the stabilising presence of IF-3 compared to initiation at the A-protein cistron, where seven such base pairs are possible Such a view is consistent with the effect of IF-3 on ribosome binding to unfolded MS2 RNA, where addition of IF-3 stimulates ribosome binding to the coat-protein site but not to the other sites[48] Similarly, crude initiation factors produce a significant stimulation in the binding of high-salt-washed ribosomes to the R17 initiator regions This effect is about elevenfold, eightfold and fourfold for the coat-protein, replicase and A-protein sites, respectively[26]

Table 2 3'-terminal sequences of 16S rRNA

E coli B	GAUCACCUCCUUA$_{OH}$ (ref 29)
P aeruginosa	G(X)₂PyCUCUCCUU(A)$_{OH}$*
B stearothermophilus	G(X)~₅PyUCCUUUCU(A)$_{OH}$*
B subtilis	G(X)~₇PyCUUUUCU$_{OH}$
C crescentus (ATCC 15252)	G(X)₃PyUCCUUUUCU$_{OH}$

Bacteria in mid-log phase were converted to protoplasts and extracted with a solution of phenol/cresol-aminosalicylate (see ref 29 and legend to Table 1) For all bacterial species examined, chromatography on DEAE-Sephadex of T₁-ribonuclease digests of terminally-labelled 16S RNA demonstrated the presence of a large ($\geqslant$12 nucleoside residues) 3'-terminal T₁-oligonucleotide X represents any nucleoside other than guanosine A more detailed account of the sequences and their determination is in preparation

*The variable presence of the 3'-terminal adenosine in 16S RNA is found in a variety of bacteria and depends on the culture conditions A more extensive examination of this phenomenon will be the subject of a separate report

*The sequence given represents that containing all or part of the conserved sequence 5′-AGGAGGU-3′ from the A-protein, replicase and coat-protein initiator regions of R17 RNA The initiator AUG is located eight to nine bases to the 3′-side of this sequence Apart from the G→A transition (see below), these sequences are identical to those available for the corresponding regions of f2 (ref 15) and MS2 RNA (refs 18, 21, 22 and 40)

†Two sequences have been reported for this region of the coat-protein binding site in the two different R17 stocks used[6,41], the G→A transition probably represents a spontaneous mutation which occurred after the two stocks were separated[41] Such a transition may have some selective advantage since it would increase the stability of interaction between the coat protein initiation site and the 3′-end of 16S RNA The corresponding sequence from MS2 (refs 22 and 40) and f2 RNA (ref 15) contains the A substitution The *in vitro* ribosome-binding data were obtained with R17 RNA containing the GGGG sequence[6,38] and with f2 or MS2 RNA presumably containing the GGAG sequence[2,8,27,28]

‡The apposition of a G and a U residue in the proposed helical region formed between the coat-protein binding site and 16S RNA would cause little, if any, destabilisation of the base-paired structure[42,43]

The bacterial protein, factor ι (interference factor), also modifies cistron selection in the translation of coliphage messengers by bacterial ribosomes Significantly, it seems to be identical to the fractional 30S ribosomal protein S₁ (ref 49), which can be linked chemically to the 3′-terminus of 16S RNA *in situ*[50] and which is necessary for the specific, initiation factor-independent binding of 30S subunits to mRNA (ref 4)

Factor ι is also identical to the α-subunit of the Qβ replicase complex[51], the presence of the α subunit is essential for the binding of the replicase to the 3′-terminus of the Qβ+strand[52] The 3′-sequence of this RNA is UCUCCUCCCAₒₕ (ref 53), and the 3′-sequence of 16S RNA is UCACCUCCUUAₒₕ, that is, they both share the sequence CCUCC which we propose to be involved in interaction with ribosome-binding sites As factor ι has a specific affinity for certain polypyrimidine tracts in RNA (ref 54), its complex regulatory function may relate to a capacity for recognising such nucleotide sequences in mRNA and at the 3′-terminus of 16S RNA

The inhibitory activity of factor ι on the translation of

coliphage RNA is restricted to initiation at the coat protein cistron[55] and is a function of mRNA concentration[54-,56] This effect may be the result of both a direct binding of factor ι to a region of the mRNA close to the coat protein initiation site[56], particularly at high concentrations of factor ι, or to a competition between the factor and mRNA for a ribosomal site[54], possibly the pyrimidine-rich 3′-end of 16S RNA It has recently been proposed that factor ι bound to the ribosome may be directly displaced by added mRNA (ref 54), the efficiency of which may depend on the sequence of nucleotides on the mRNA to which the ribosomes bind Thus initiation at the R17 coat-protein binding site, which can form only three to four base pairs with the 3′-terminus of 16S RNA, is inhibited by the presence of factor ι (refs 54–56), whereas initiation at the A-protein site (7 possible base pairs) is unaffected[55]

The ribosomal protein S₁₂ is also clearly involved in specific initiation on mRNA (ref 12) However, its role may result from its ability to interact with initiation factors on the 30S subunit[12], perhaps potentiating the specific recognition by the 3′-end of

16S RNA Using bifunctional cross-linking reagents it has recently been shown (Heimark, R , and Traut, R T , and Bollen, A , Kahan, L , Cozzone, A , Hershey, J W B and Traut, R R , quoted in ref 49) that S_1 (factor *i*), S_{12} and IF-3 give cross-linked products in the 30S subunit, and are presumably close to the 3'-end of 16S RNA, since S_1 can be chemically linked to the 3'-terminal nucleoside[50]

We therefore propose that the cistron specificity of bacterial ribosomes previously ascribed to the 30S subunit, can be further localised to a pyrimidine-rich stretch of about ten nucleotides at the 3'-terminus of the 16S ribosomal RNA We suggest that the degree of complementarity of this region with a purine-rich segment within the ribosome binding site sequence on bacterial mRNA determines the intrinsic capacity of the ribosome to translate a particular cistron The finer controls imposed on initiation at different cistrons may involve both the accessibility of the purine-rich segment to the 3'-terminus as determined by the secondary structure of the initiation region, and the availability of certain initiation factors which would modify the proposed interaction

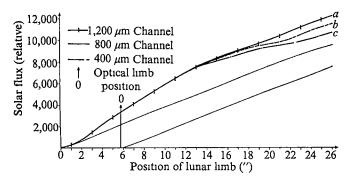
Submillimetre brightness spike at the solar limb

WE report here the first complete phase of the reduction of data obtained during the solar eclipse of June 30, 1973 from the high altitude moving platform provided by Concorde 001 Reports of the flight[1] and of an optical measurement of chromospheric thickness[2] are already published Submillimetre observations were made at both the second and third contacts, using a rapid-scanning Michelson interferometer At the second contact one complete interferogram of resolution 1 cm^{-1} was measured each second, but the limited passband of the detector, an InSb Rollin instrument[3], was found to have attenuated the highest frequencies (above 200 Hz) so these data have not been used At the third contact 10 s were taken per interferogram The instrument response was satisfactory, but the record needed subsequent digitisation, rendering analysis much lengthier, since an electronic analogue Fourier transformer had been built for 1 s interferograms, but was not usable for the 10 s data

Figure 1 shows a plot of solar flux against the lunar limb position in 3 passbands, centred at 400 μm, 800 μm, and 1,200 μm Radiation from the image of the revealed solar crescent, plus that from the lunar disk, and from the sky field

was plotted against time in each band Time was then correlated with the limb positions using aircraft coordinates and astronomical data The lunar and sky contributions were then subtracted, leaving the solar contribution as a function of the distance of the lunar limb from the solar optical limb Corrections for several effects were taken into account First, for atmospheric emission and absorption, the latter averaging less than 10% in the shortest, most obscured waveband Second, for spectrally selective absorption and emission by the 12 mm thick, crystal quartz, window of the aircraft Third, for spectrally selective absorption by the TPX lenses in the spectrometer and the TPX detector window Finally, for the wide lobes of the 12-cm telescope, which had 30' diffraction limited resolution at 1,200 μm The sky brightness temperature above 1,200 μm averaged 15 K above 57,000 feet, giving an accuracy limit of 1% of the total signal, which limited the relative radiometry

The separate contributions from the whole lunar disk and from the sky were measured with considerable precision during the approximately 65 min of submillimetre totality, by integrating alternately on and off the image of the lunar disk During the 7 min observing time starting at the origin of Fig 1 the power on to the detector from the Moon, within the instrument passband, was 3×10^{-8} W, from the sky it averaged $1\ 5 \times 10^{-8}$ W The power from the solar crescent when the optical


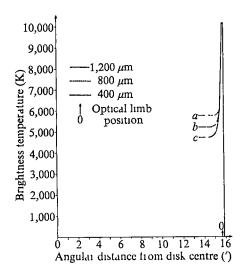


Fig. 1 Flux from the Sun against the lunar limb position in 3 submillimetre wavelength bands Error bars shown on the 1,200 μm curve apply closely to the other wavelengths Two lower plots show computed fluxes from theoretical models with no limb brightening Arrow indicates the position of the optical limb

limb was just revealed, at point 0, was estimated to be 1 5× 10⁻⁹ W The minimum detectable signal, expressed as the noise equivalent power resulting from the combined detector noise and the local emission noise was 8 × 10⁻¹² W Hz⁻¹ Thus, integration times of the order of seconds, and the dynamic range of 10³ to 1, yielded good signal-to-noise ratios in each of the 3 wavelength channels Nevertheless, a multichannel radiometer would have given superior values in this non-detector noise limited broad-band regime

Also shown in Fig 1 are computed curves for solar disks of a constant brightness temperature of 5,750 K, together with radii equal to the optical radius and 6" larger, respectively These show that there is an excess at the limb both geometrically and thermally distinguishable from 'flat-topped' distributions This is displayed clearly in Fig 2, which assumes circular symmetry about the centre of the solar disk The plots have a resolution, obtained by smoothing curves with an original 0 8" discrimination, of 1 6" That is superior by a factor of 25 to the resolution obtained, at 1,400 μm only, with the largest ground based millimetre-telescope[4], and by a factor of 50 to the resolution obtained in the two submillimetre wavebands[5] The brightness spike at the limb has been normalised to fit a brightness temperature, T_B at the centre of the disk, of 5,750 K in the 1,200 μm band A good fit to the

Fig 2 Brightness temperature against angular distance from the centre of the solar disk Dotted curves are partly extrapolated The solid curve, common to all three channels, is normalised at peak Arrow indicates the position of the optical limb

observations was then obtained by assuming the peak of the spike at 800 μm and 400 μm to have the same T_B value (10,100 K) as at 1,200 μm That leads to extrapolated disk temperatures at 800 μm and 400 μm of 5,200 K and 4,700 K, respectively, which are in reasonable agreement with previous measurements[6,7] As only 19" of photospheric disk were observable, however, these extrapolations rely heavily on a model which assumes that the Sun is a diffuse emitter except for the source responsible for the observed spike

The very limited angular extent of the excess emission, which extends from some 4" outside the optical limb, where it exhibits a very steep cutoff, to 5" within the optical limb, with a less steep decline, suggests that the spike can be identified with emission from chromospheric spicules This geometrical interpretation of the excess emission is corroborated by the apparently small change of peak temperature with wavelength Models of spicules from data at optical wavelengths[8], imply that each spicule is optically thick throughout the submillimetre range Though sparsely distributed, their superposition at the limb is here seen as the edge of a thin sheet at temperatures of the order of 10,000 K A more detailed analysis should yield information on the number density and length distribution of the spicules above the photosphere, in the region near the chromopause

Although an occultation experiment of this type is well suited to examining the large scale brightness distributions across the Sun, the limited time that was available after the third contact in this case has prevented such an examination here The mystery of the submillimetric limb brightening, missing on an arc minute scale[7,9] thus remains

Circular polarisation in HDE226868

MUCH effort is being expended to develop an understanding of the details of X-ray production in some astronomical sources Accretion on to magnetic poles is the mechanism most often invoked for X-ray production in collapsed stars Strong magnetic fields, such as those associated with collapsed objects, are capable of producing observable circular polarisation, so it is of great interest to determine whether HDE226868, the binary containing Cyg X-1, exhibits this effect

Nikulin, Kuvshinov and Severny[1] reported circular polarisation from the light of HDE226868 that varied with time between 1 2% and 2 1% Subsequently, Gehrels[2], using a matching

Table 1 Time-averaged circular polarisation values for HDE226868

Filter	n	$(10^4) q \pm \sigma q$
U	2	$+ 1 7 \pm 4 1$
B	8	$+ 2 9 \pm 0 9$
V	1	$+ 4 0 \pm 3 0$
r	3	$- 5 1 \pm 0 9$
Infrared	1	$- 4 6 \pm 2 5$

colour response, observed no significant circular polarisation down to a level of about 0 05% Furthermore, he found no polarisation in the visible or ultraviolet regions down to levels of about 0 1%

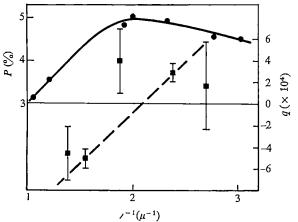
Using the photoelastic polarimeter and 31-inch telescope at Battelle Observatory[3], we have obtained circular polarisation measurements of Cyg X-1 on nine nights during June–October, 1974 (Table 1) The fourth Stokes parameter V, normalised to unit intensity, is denoted by q, and n is the number of observations for a given filter Positive circular polarisation refers to counterclockwise rotation of the electric vector in a fixed perpendicular plane for an observer facing the source The effective wavelengths are 3,700, 4,200, 5,350, 6,450, and 7,250 Å for the U, B, V, r, and infrared filters, respectively The half-power transmittances are $\lambda\lambda$ 3,450–3,900 Å, $\lambda\lambda$ 3,800–4,750 Å, $\lambda\lambda$ 5,100–5,700 Å, $\lambda\lambda$ 6,000–7,200 Å, and $\lambda\lambda$ 6,750–7,800 Å


Fig. 1 Linear (●) and circular (■) polarisation of HDE226868 as a function of wavelength The linear polarisation is taken from Gehrels[2]

There is definite circular polarisation (≥ 3 σ) in two filters (B, r) The wavelength dependence of the linear polarisation, as presented by Gehrels[2] and plotted in Fig 1, suggests interstellar polarisation Coyne, Gehrels, and Serkowski[4] predict a maximum linear polarisation at about, 5,000 Å From calculations based on the analysis of Martin[5], we expect a circular polarisation near zero at this wavelength, and in the blue and red regions we expect approximately the same magnitude, but opposite handedness for q, this is roughly what is seen in Table 1 and Fig 1 Narrow-band measurements of both the linear and circular polarisation over the entire spectrum would help to separate interstellar and any possible intrinsic effects

The case for interstellar dust as the source of the circular polarisation is strong But the interest in this object warrants further polarimetric investigations

Evidence for mantle heterogeneity from two large seismic arrays

OBSERVATIONS from two large seismic arrays suggest that lateral heterogeneity is present throughout the Earth's mantle The differences between seismic event locations determined by the arrays and event locations determined by a global network of seismic stations indicate that seismic rays are deflected by velocity anomalies in the mantle

A large array can be used to locate seismic events because it provides a direct measurement of the azimuth and inclination (or wave slowness $dT/d\Delta$) of incoming teleseismic P-waves Such locations, however, are usually inaccurate because they are very sensitive to the effects of structure along the propagation path By contrast, locations determined by a global distribution of seismic stations and reference to standard travel time tables are accurate to within 30 km because the effects of small scale structure in the crust and mantle have been averaged out

Davies and Sheppard[1] suggest that large errors in event locations determined by the Large Aperture Seismic Array (LASA) must be attributed to lateral heterogeneity in the mantle If most of the heterogeneity is a long way from LASA, other arrays which sample the same source regions and approximately the same propagation paths should show similar mislocation tendencies I have determined locations for teleseismic events recorded at a large seismic network situated near Hanford, Washington The network contains 24 permanent stations, irregularly distributed within an area roughly 100×150 km All stations consist of 1-s vertical seismometers, modified to record higher frequency microearthquake activity This precludes detection of teleseismic events with magnitudes below 5 7, so that only about 200 acceptable events were recorded between 1970 and 1972 Two stations were eliminated because their travel time residuals show anomalously high scatter, the remaining 22 stations form the Hanford array Arrival times were chosen visually at the first coherent peak or

Fig 1 The Hanford array diagram The radial axis is $dT/d\Delta$ and the polar axis is array to event azimuth Each arrow represents a mislocation vector for one event, the head is the true location and the tail is the apparent location Mean vector 0 38 s per degree along azimuth 245 ° removed as described in ref 1

trough Reading accuracy is about 0 1 s which limits the accuracy with which events are located to ~ 200 km

The azimuth and $dT/d\Delta$ of incoming teleseismic signals were determined by a least squares fit of the best plane wave to the uncorrected data These quantities, together with the azimuth and $dT/d\Delta$ values predicted by the United States Coast and Geodetic Survey (USCGS) "preliminary epicentre" locations and reference to the Jeffreys–Bullen (JB) tables, were plotted on an array diagram (Fig 1) Seismic source regions can be located using Fig 2

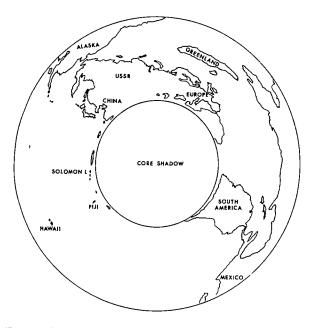
A first order correction[1] for the effect of gross structural trends directly beneath the array has been applied to the data of Fig 1


Fig 2 The coastlines of the world as viewed through an array diagram centred on the Hanford array, assuming that the JB tables for P-phases are correct This map was created by R Sheppard

The Hanford array mislocates most seismic events Systematic mislocations are associated with several source regions such as Russia, the Ryukyu, Bonin and Solomon Islands and the northern portion of South America Rapid variations in both azimuth and $dT/d\Delta$ anomalies are also present, notably associated with events from the southern end of the Solomon Islands, the coast of Chile and the island of Hokkaido

An array diagram for LASA is shown in Fig 3 The coastlines of the world as viewed through an array diagram centred at LASA are very similar to those shown in Fig 2 LASA also systematically mislocates events from several source regions, and the direction of mislocation is strikingly similar to that observed in the Hanford array diagram Some of these features are more easily seen in Fig 4

The similarities in the global pattern of mislocations for the arrays suggests that structure at considerable distance from the arrays is responsible for most of the mislocation The only alternative explanation requires nearly identical structure beneath both arrays which is unlikely My analysis supports the suggestion[1] that most of the mislocation is a result of lateral heterogeneity in the mantle

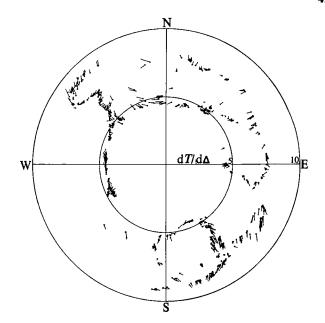
Azimuth and $dT/d\Delta$ anomalies associated with several source regions are too large to be attributed to structure associated with descending slabs of lithosphere[1–4] Most of the orientations of the mislocation vectors show no obvious correlation with the dip of the descending slab or with depth to source There is a tendency, however, for the orientations of the mislocation vectors to change from one trench region to the next, as shown by the data for the Hebrides and Solomon Islands


Fig. 3 An array diagram for LASA Data used to construct this diagram are the same as those used by Davies and Sheppard[1] Mean vector removed as in ref 1

(Fig 4) Similar effects are seen in the LASA data This suggests that structure close to the source regions must be responsible for at least part of the observed mislocation As the descending slab cannot be responsible, it seems that we are observing the effects of structure on deeper interfaces such as the 630 and 800 km discontinuities

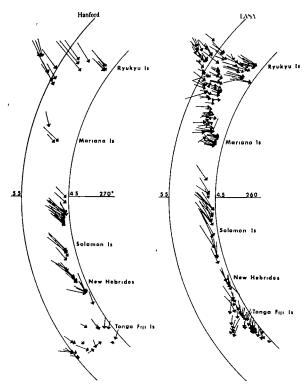
Events from Russia seem to be arriving 5° off azimuth at both LASA and Hanford A significant difference should be observed between the average JB time residuals calculated for each array if the incoming wave fronts were deflected at great distance from the arrays, for instance in the deep mantle, and were not seriously distorted during their subsequent traverse to the Earth's surface The magnitude of the time


Fig 4 Enlarged portions of the LASA and Hanford array diagrams

difference is approximately $t = H\cos\theta\,\delta\theta/V$ where H is the distance between the arrays, θ is the angle between the line connecting the arrays and the wavefronts (if the wavefronts suffer no distortion) $\delta\theta$ is the azimuth anomaly and V is the apparent velocity of the waves as they sweep across the array For the Russian events, $H = 900$ km, $\theta = 6°$, $\delta\theta = 5°$ and $V = 22$ km s^{-1}, the expected time difference is about 3 5 s This has not been observed Even allowing for dissimilar $dT/d\Delta$ anomalies at each array and for variations associated with travel time data[5] it is extremely difficult to mask an expected time difference of 3 5 s This suggests that similar structure in the upper mantle directly beneath both arrays may be responsible for the mislocation of Russian events But the general agreement in the global pattern of mislocations at both arrays suggests that upper mantle structure beneath the arrays is not responsible for most of the features in the array diagrams

Hydrothermal metallogenesis in the Bauer Deep of the south-eastern Pacific

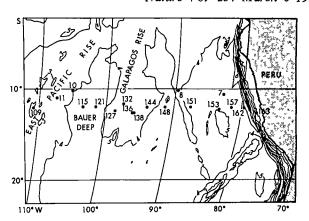
SEDIMENTS from the East Pacific Rise that are unusually enriched with iron, manganese, and other metals[1,2,3] are correlated with areas of high heat flow on oceanic ridges With the discovery that sediments rich in iron directly overlie oceanic basaltic basement, it has been suggested that such deposits were formed by circulating hydrothermal fluids generated during mid-oceanic rift volcanism[4,5] Other suggested origins are authigenic precipitation of iron and manganese from seawater[6], submarine weathering of basaltic debris, and precipitation during diagenetic remobilisation of manganese


Fig. 1 Index and core location map showing general bathymetry in the 12°S region of the Nazca plate

in the sediment column[7] Our geochemical evidence supports the hydrothermal metallogenesis hypothesis

The Bauer Deep, located between the East Pacific Rise and a fossil spreading centre, the Galapagos Rise[8], is an area of sediment accumulation rich in metals (Fig 1) This sediment may originate from East Pacific Rise crest exhalations that are transported into the Bauer Deep[9] Heat flow values for the Bauer Deep are larger than values for other oceanic basins of the same age[10], the anomalously high heat flow values in the Bauer Deep with their large variability and bimodal distribution are characteristic of mid-oceanic ridge heat flow patterns Anderson and Halunen have suggested[10] that metal hydroxide precipitations formed by hydrothermal exhalations within the Bauer Deep produce the metal-rich sediments there This is borne out by our geochemical evidence based on element distributions and accumulation rates across the Nazca lithospheric plate

The surface layers (0 to < 10 cm) of 12 cores were analysed for metal content Chemical compositions were determined by X-ray fluorescence spectrometry and atomic absorption spectrophotometry On four of the cores, sedimentation rates were determined by the logarithmic decrease of unsupported ^{230}Th with depth in the sediment The core length over which the unsupported ^{230}Th activity decreased by one-half was divided by 75,200 yr, the half life of ^{230}Th This method has been successful on Quaternary pelagic sediments[11-13] Metal accumulation rates were calculated by multiplying the bulk sedimentation rate by the metal content, assuming an *in situ* dry uncompressed bulk density for pelagic sediments of 0 75 g cm^{-3} (ref 14)

Figure 1 shows the location of 18 cores analysed during a larger study of their chemical and mineralogical composition (G M McM , unpublished) The transition metal, aluminium and calcium carbonate contents of 12 of these cores are presented in Table 1 Figure 2 shows the distribution of iron, manganese and four trace metals on a profile across the Nazca plate at approximately 12°S The metal concentrations were normalised to aluminium in a method similar to that of Piper[15], who found that the metal concentrations of East Pacific Rise sediments showed more internal consistency and exhibited stronger maxima near the rise crest when treated in that way than when plotted on a carbonate-free basis

In the Bauer Deep, enrichment is greatest for iron, manganese, copper, and nickel (Fig 2) Iron and manganese distributions correlate well with each other across the entire area, but those of other metals do not Nickel and copper show greatest enrichment in the Bauer Deep and Galapagos Rise sediments, and some covariance with iron and manganese Cobalt and chromium show no enrichment and display no covariance with the other transition metals We interpret the strong iron and manganese covariance as evidence for coprecipitation of iron and manganese hydroxyoxides[9] The distributions of nickel and copper are similar to those of iron and manganese and those metals may therefore be fixed in the same manner But hydrothermally derived iron oxides may at least partially scavenge manganese and associated metals such as nickel and cobalt from seawater by catalytic oxidation[16] The distribution of chromium may be explained by its mobility in the oxidising environment of the sediments, as it forms soluble complexes in the hexavalent state[17] The cobalt distribution generally follows that of chromium, although greater enrichment would be expected because cobalt should not be as mobile as chromium in these sediments

The transition metal accumulation rates of four cores representing Quaternary sedimentation on the East Pacific Rise, the Bauer Deep, the Galapagos Rise, and on the plate near the

Table 2 Surface sediment accumulation rates

Core no	Region	Sedimentation rate (cm per thousand years)	CaCO₃—free sedimentation rate (cm per thousand years)	Accumulation rates (mg cm⁻² per thousand years)					
				Mn	Fe	Cu	Ni	Co	Cr
109	East Pacific Rise	1 08	0 11	0 88	0 73	0 08	0 07	0 03	0 03
115	Bauer Deep	0 19	0 18	6 98	19 4	0 11	0 15	0 03	0 01
132	Galapagos Rise	0 20	0 05	1 16	2 03	0 03	0 06	0 01	0 01
7	Eastern Plate	0 23	0 23	0 65	8 28	0 03	0 05	0 01	0 03

Peruvian coast are presented in Table 2 The bulk sedimentation rate across the plate is approximately 0 2 cm per thousand years except for the East Pacific Rise crest, which shows a higher rate attributable to carbonate deposition Bender et al[18] determined manganese accumulation rates for pelagic sediments and nodules They found that the manganese accumulation rates for pelagic sediments ranged from 0 2 to 3 2 mg cm⁻² per thousand years with an average value of 1 3 mg cm⁻² per thousand years But an accumulation rate of 35 mg cm⁻² per thousand years was found for a core taken farther south than ours on the East Pacific Rise crest[6] This rapid rate of accumulation may be further evidence that manganese and other transition metals are derived from ridge–crest volcanism Our data show that manganese is accumulating on the East Pacific and Galapagos Rises at 12°S at a rate close to the average pelagic value, but that in the Bauer Deep it is accumulating at more than five times that rate Accumulation rates for iron, copper and nickel are similarly higher in the Bauer Deep sediments than in those from the other areas

Our data indicate that metal-rich sediments can be derived locally in areas of great heat flow such as the Bauer Deep and need not be formed exclusively at an active spreading centre and transported elsewhere The transition metal to aluminium maxima found by Piper[15] for the East Pacific Rise crest and the

rapid manganese accumulation rate established by Bender et al[6] have been used as evidence for local volcanism as the source of these metals Our data provide a similar argument for the Bauer Deep iron and manganese would seem to be the direct products of volcanism A direct relationship with volcanism is not as clear for the other transition metals

In areas where the accumulation rates are close to those of average pelagic sediments, authigenic precipitation is probably a significant factor for metal enrichment, and submarine weathering must also make contributions in areas of slow sedimentation where authigenic minerals such as phillipsite are forming[7,19] Diagenetic remobilisation of manganese is unlikely, however, in oxidised pelagic sediments

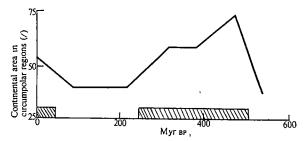
Fig 1 Variation of continental area within 30° of poles as a function of time The shaded parts of the time axis include all extensive glaciations[4,5]

Long term variations in the albedo and surface temperature of the Earth

THE surface temperature of the Earth depends primarily on the solar constant, the Earth's albedo and the total mass and chemical composition of the terrestrial atmosphere Studies of climate covering the past few million years have generally allowed for variations in albedo in calculating average values of the surface temperature But over longer periods of time, however, less allowance has been made for albedo variations, it has, indeed, frequently been assumed that the albedo, when averaged over a long enough time, can be taken to be constant (see ref 1) We wish to point out that, on the contrary, long term variations in the albedo can be expected to occur, and to produce significant changes in the average surface temperature

The total albedo of the Earth depends on the relative proportions and dispositions of the continents and oceans and their related cloud covers This varies both because the cross section presented to incident solar radiation by a given area depends on its latitudinal position, and because the variation in reflectivity with angle of incident radiation changes from land to ocean Throughout much of the geological record, the relative amounts of continent and ocean do not seem to have undergone major change, but the relative disposition of the two has varied considerably because of continental drift The amount of land area, as distinct from continental area, has certainly undergone fluctuations, but no systematic trend appears either in time, or relative to the disposition of the continents on the Earth's surface We have estimated the average surface temperature of the Earth using a computer program which allows both for the greenhouse effect of the atmosphere and for variations in albedo resulting from different positions of the continental masses, but which assumes no significant change in the ratio of land-to-ocean area (Surface temperatures have been computed as a function of latitude for land and ocean separately, and an average, weighted according to the areas involved, has then been calculated)

If cloud cover is initially ignored, the important factor is the latitudinal distribution of the continents We have therefore looked especially at two extreme cases (1) where the continents are gathered together into a belt round the equator, (2) where they form a cap round one, or both, poles We have constructed semi-empirical curves of reflectivity as a function of the angle of incident radiation, assuming in case (1) a covering of soil, and in case (2) an ice–snow covering Although considerable information is available on the albedo of different types of surface, data on the variation of albedo with solar elevation are less well determined[2]. Fortunately, computer runs using a range of possible albedo variations with angle indicate that only minor changes are produced in the surface temperature with any reasonable functional relationship The difference in albedo between the two models is found to change the surface temperature by more than 12 °C (the higher temperature corresponding to the equatorial position of the continents) Since the difference between a glacial and an interglacial period probably corres-

ponds to a change in average temperature of only 5 °C (ref 3), this albedo-dependent variation must be regarded as significant


There are, however, two modifications that should be made First, we have assumed extreme dispositions of the land-masses in deriving this figure for the surface temperature More probable variations in the latitudinal position of the centre of area of the continents will still lead to differing values of the albedo, and therefore to differences in surface temperature, but the change will be smaller than that derived above Similarly, the effect of introducing cloud cover into the calculations, for any likely cloud distribution, is to reduce the change in albedo and so the variation in surface temperature Nevertheless, after allowing for both these factors, the amount of latitudinal change postulated in reconstructions of continental drift still seems from our estimates to be capable of producing a variation in surface temperature of a few degrees The effect of this would be to accentuate the prevailing climatic conditions In particular, although a land-mass near one of the poles would, in any case, be expected to have an ice–snow cover, a resultant slight lowering of the average temperature, as a result of the albedo effect, could turn this into a major glaciation The effects of this could then extend to appreciably lower latitudes than would otherwise be the case Whether or not this occurs will depend on other astronomical and geological factors What we can assert is a statement of probability that the likelihood of extensive glaciation occurring should be greater when a higher proportion of the land mass is near the poles

We have used the data cited by McElhinny[4] to derive values for the latitudinal distribution of the continents during each geological period The results are best represented in terms of the percentage of the terrestrial surface within 30° of each pole which is covered by continent The reason for choosing this form of presentation for the data is that continental displacements at lower latitudes, although leading to small changes in the albedo, cannot support extensive glaciation It is the latter that can most readily be detected in the geological record

Some of the data on continental drift remain uncertain In particular, information on continental drift and major glaciations in the Precambrian is still inadequate for the type of comparison we wish to make here Nevertheless, as can be seen from Fig 1, if we separate out the periods during which extensive glaciations most commonly occurred[5], these correlate reasonably well with periods when a higher percentage of the circumpolar regions was occupied by continents Within the limits of accuracy of the data, therefore, predictions based on the albedo effect are supported by the available geological evidence

Recent changes in Atlantic surface temperatures

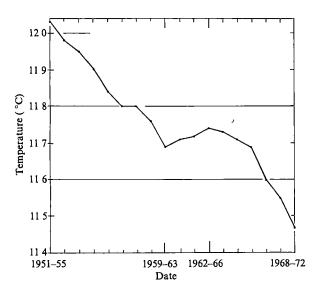
RODEWALD recently published brief notes about the temperature measurements of the sea surface made by nine North Atlantic weather ships during the past two decades[1,2] His remarks were prompted by the regrettable fact that several of these ocean stations are being discontinued, a decision which will make it much more difficult to monitor the temperature trends in the North Atlantic He presented[1] average annual temperature values for overlapping 5-yr periods, showing a distinctive decrease of 0 56 °C from the 1951–55 period to the 1968–72 period (Fig 1) Rodewald also provides[2] three important maps the changes in surface temperatures from 1951–55 to 1968–72


Fig 1 Running 5-yr mean surface temperature at the nine North Atlantic fixed station weatherships, according to Rodewald[1]

for the annual mean, and for the months of February and August Figure 2 shows his analysis of the February changes There is a remarkable consistency in the values, for example, at Station D (44°N, 41°W) the surface temperature declined by 1 61 °C in the annual average, by 2 12 °C in February and by 2 10 °C in August These are surprisingly large changes over such a short time span Since they are based on a well defined homogeneous record of careful observations there can be no doubt that they are real The core of decreasing temperature lies along the north edge of the Gulf Stream extension, suggesting a south eastward shift of that current and replacement with Labrador Current waters, especially in the vicinity of the Grand Banks The largest changes are encountered across the Atlantic between 40° and 50°N

Here we attempt to put Rodewald's maps into perspective by comparing them with maps of surface temperature change for other time intervals, so that one can assess the significance of the changes he depicts One of these may be obtained by subtracting the temperature pattern obtained by the CLIMAP group[3] for the most recent ice age (approximately 18,000 yr ago) from the recent pattern (Fig 3) The CLIMAP pattern was constructed by objective methods from the assemblages of fossil planktonic foraminifera in approximately 90 deep-sea cores

Values north of 50°N could not be determined with great accuracy as, according to the ice-age map, temperatures there are given as 'below +2 °C' The differences cannot, however, be much larger than approximately 12 °C near 45°N and less farther north, since the current temperatures at these latitudes are not higher than +12 to +13 °C The CLIMAP charts from which Fig 3 was derived clearly show that the long tongue of maximum anomaly along 45°N results from a southward shift of the maximum temperature gradient at the north edge of the Gulf Stream extension

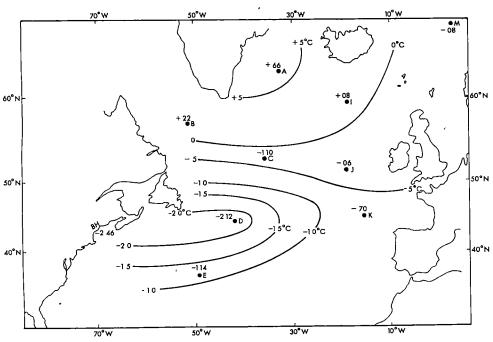
In Fig 2, the values of the 22-yr change in February temperatures given by Rodewald are entered at the various weather ship station locations At Station D, for example, (indicated also on Fig 3) the 22-yr recent change of February surface temperature was −2 12 °C This station is located in the area of maximum change between the most recent ice age and today, the estimated change was about 11°C So it seems that we have experienced, in the past 29 yr or so, a change in Atlantic ocean temperatures which amount, in the Gulf Stream vicinity, to about one-sixth of the difference between total glaciation and our present climate


Fig 2 Change of February North Atlantic surface temperature from the 1951–55 pentade to the 1968–72 pentade, according to Rodewald[2] (Data for this figure would support an analysis even more consistent with that of Fig 3 than Rodewald's analysis)
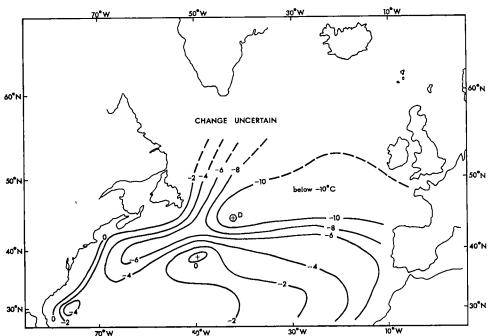

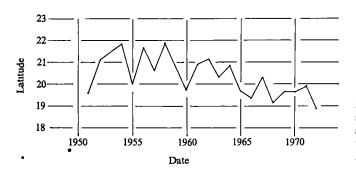

Fig. 3 Difference between ice age surface temperatures, (approximately 18,000 yr ago) and present winter surface temperatures, derived from the CLIMAP reconstruction[3]

Another comparison may be made with the map of average North Atlantic surface water temperature change between the early 19th century and the 1887–1899, 1921–38 period given by Lamb[4] Rodewald's figures approximately mirror those given by Lamb, indicating that the change from 'Little Ice Age' conditions to the early part of the present century was just about wiped out between 1951 and 1972 The 'Little Ice Age' thus seems to have been a return of about one-sixth of the way to a full ice age Rodewald's map in turn indicates that, at least as far as surface temperatures in the North Atlantic are concerned, the pattern had returned roughly to 'Little Ice Age' conditions from its early 20th century excursion by 1972

Two other pieces of information tend to confirm the relative magnitude of the surface temperature change given by Rodewald First, in West Africa during the same 1951–72 period, the northern edge of the monsoon drifted irregularly southward, as indicated in Fig 4 Assuming that if this displacement persisted at the 1968–1972 latitude the biotic zonation would adjust similarly, a comparison may be made with the late glacial zonation as given by Cloudsley-Thompson[6] Once again the 1951–72 shift seems to have been about one-sixth of the late glacial to present displacement

The second observation is the change of worldwide annual average snow and ice cover reported by Kukla and Kukla[6] In the northern winter of 1971–72 there was a rapid increase of snow and ice cover which persisted into the following years This increase was also about one-sixth of the difference between present-day conditions and those at the end of the most recent glaciation

We do not have an adequate basis for estimating whether or not the changes observed in the 1951–72 period will continue to grow, but it is essential to monitor further development with great care Indeed, we do not know whether the pattern of 1974 represents an end to the trend of the previous two decades or simply a temporary reversal like those which have characterised individual years of those decades on occasion But we should not assume that the change indicated by Rodewald's data is just a short term passing anomaly easily reversed in a year or so

Fig. 4 Northward penetration of the monsoon rains in West Africa in the longitudes of Nigeria The higher the latitude to which the rains penetrate, the greater the seasonal rainfall The latitude of the northern edge of the monsoon rains was obtained by least squares fitting of a trend line to the rainfall amounts at various stations in the longitudes of Nigeria The intercept of this line with zero rainfall was taken as the northern edge of the monsoon Few stations north of this calculated position reported more than a few millimetres of rainfall Plotted points are averages of the July and August values

Buckle propagation in submarine pipelines

DURING its construction a submarine pipeline is at the same time bent and loaded by the external pressure of the sea If it is bent too far, it buckles If the local external pressure is small, the buckle is limited to a short kink on the compressed side of the pipe But if the external pressure is large enough, the local bending buckle can transform itself into a buckle of a different form, which once initiated can propagate along

the pipe, driven by external pressure alone, even into regions free of bending. Figure 1 shows a pipe along which a buckle has propagated in this way. The mode can be observed by grasping a tube of toothpaste firmly between thumb and forefinger, and then moving the fingers along the tube. In a short transition region, between the fingers, the pipe bends from a circular into a dumb-bell cross section.

This problem is important because of the possibility that a mishap during pipelaying might initiate a buckle which would run along the completed section of a pipeline, perhaps for many kilometres, at a cost of the order of $1.5 million a kilometre. Little has been published about this problem[1]. We describe the results of a preliminary analysis and of some tests on model pipes, and concentrate on determination of the minimum pressure needed just to sustain propagation. Buckle

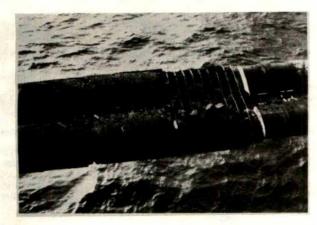
Fig. 2 Dimensionless propagation pressure $p(R/t)^2/Y$ as a function of R/t. Points indicate experiments on stainless steel tubes of diameter 50.8 mm (■) and 12.7 mm (▲). — — — —, Predicted by simple theory.


Fig. 1 Pipeline collapsed by a propagating buckle. The test was carried out on steel pipe of outside diameter 813 mm and wall thickness 19.1 mm.

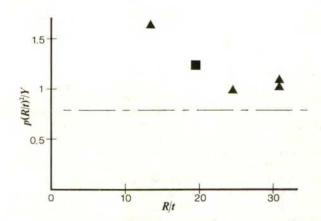
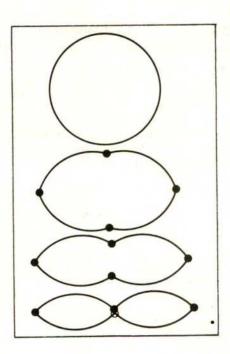
propagation of this kind is distinct from the classical phenomenon of elastic buckling of cylinders under external pressure[2]; in a typical pipeline the propagation pressure is about a third of the elastic critical pressure.

A pipeline is essentially a steel tube with radius:thickness ratio of the order of 20, cold formed from a medium strength ductile steel and surrounded by a concrete weight coating (which contributes little to its strength). It can be treated as a thin shell. We begin by considering the kinds of deformation such a shell can undergo. It can either deform inextensionally, in a mode which bends the middle surface but does not stretch it, or extensionally, in a mode which both stretches and bends the middle surface. In general, the amount of energy required to deform the shell in an inextensional mode is much less than that to produce a deformation of similar magnitude in an extensional mode[3]; the shell 'prefers' to deform inextensionally if it can. Rayleigh showed, however, that if a cylindrical shell is constrained so that one circumference undergoes no deformation, then no purely inextensional deformation is possible[3]. Although there is thus no way in which the buckle can propagate without any stretching of the middle surface, it will develop a buckle configuration in such a way that the pipe is distorted by bending as much as possible and stretching as little as necessary.

An estimate of the propagation pressure can be made by assuming a buckle to move along the pipe in an unvarying mode (so that an observer moving with it would always see the same buckle configuration), and equating the work done by the external pressure on the consequent volume change to the work required to deform the pipe. Since the deformation is so large, plastic deformation dominates over the effects of




elasticity, so that the pipe deforms almost as it would if it were made from a rigid-plastic material. Then if the mode of deformation is purely inextensional, the propagation pressure p will be proportional to Yt^2/R^2, where Y is the yield stress, t the wall thickness of the pipe and R its radius. Different pipes made from different materials can then be compared by evaluating the non-dimensional propagation pressure $p(R/t)^2/Y$, which will be a constant if extensional effects are not important, and a function of R/t if they are.

Figure 2 shows the results of tests in which a buckle was driven along steel tubes. It shows that different pipes may be compared in this way, and suggests that the presence of extensional deformation exerts little influence for R/t greater than 20.

A theoretical estimate of the propagation pressure can be made from the work calculation described earlier. Suppose a cross section of the pipe to deform in the way shown in Fig. 3. All the deformation is in bending, concentrated into four 'plastic hinges'[4], separated by rigid regions. Two opposite hinges move together until they meet, and the other two move

Fig. 3 Mode of collapse assumed in analysis.

apart. If the material is perfectly plastic, the work calculation gives

$$p(R/t)^2/Y = \pi/4$$

Comparison with Fig. 2 shows that this somewhat under-estimates the observed pressure. Work calculations of this kind usually overestimate plastic collapse loads, and indeed can be proved to do so in the case of small deformations. Here the deformation is not small, and the buckle must also obey an internal equilibrium condition. If the transition from the circular to the dumb-bell cross section were very long, extensional deformation would be negligible and the total work dissipated would approach that corresponding to the above equation. But more detailed examination of the forces within the pipe wall shows that a buckle with such a long transition cannot propagate, because its equilibrium would require axial forces too large for the pipe wall to carry. Instead the transition shortens until the equilibrium conditions can be met: this involves a steeper transition, more stretching deformation, and a larger propagation pressure.

Other modes than the one shown in Fig. 3 can be used in the analysis, but this one gives the lowest propagation pressure. Its final cross section agrees quite well with the one observed in experiments.

One way of avoiding the danger of pipeline collapse by buckle propagation is to design the pipe so that its propagation pressure is greater than the greatest external pressure the sea can exert. It may instead be more economical to use a thinner wall but to guard against the possible destruction of long sections of line by placing at regular intervals 'buckle arresters' which will stop buckles which have begun to propagate. The design of buckle arresters will be discussed elsewhere.

Some of this work was undertaken for British Petroleum Ltd. We thank R. Denston, J. W. Ells and G. Hutchinson for advice and help.

Xenopus from the Palaeocene of Brazil and its zoogeographic importance

THE African frog *Xenopus* (a member of the family Pipidae), formerly found in Miocene[1,2] and Recent deposits in Africa, is described here from the Palaeocene ($\sim$ 60 Myr) of Brazil. Extant pipids are aquatic freshwater frogs, occurring in sub-saharan Africa (*Xenopus, Hymenochirus, Pseudhymenochirus*) and northern South America (*Pipa, Protopipa, Hemipa*). They display a mosaic of primitive and specialised characteristics and are generally placed as an ancient offshoot of early anuran stock. Both fossil and recent occurrences of the Pipidae are consistent with an ancient distribution exclusively across the southern continent[3,5].

The Palaeocene material from Brazil consists of well pre-served, uncrushed braincase and postcranial elements, including those diagnostic of *Xenopus*—relatively narrow, flat, and un-sculptured skull roof bounded by parasagittal crests; well defined parietal foramen; paired or unpaired vomers, occa-sionally toothed; three or occasionally four acoustic foramina in the medial braincase wall; dagger shaped parasphenoid, lateral wings absent; only the inferior perilymphatic foramen present; cleft scapula; fused scapula and clavicle; iliac shaft lacking crests.

The morphological characteristics (expanded ear capsules, azygous frontoparietal, presence of parietal foramen, bilobed trochlear articulation of humeral head, far lateral position of the inferior perilymphatic foramina, short scapula, opistho-coelous (probably epichordal) vertebrae, fused sacrum and urostyle, and sacrum with widely expanded diapophyses) indicate that this frog is a member of the family Pipidae. The general head shape and the listed diagnostic features confirm our reference to the distinctive genus *Xenopus*, limited today to subsaharan Africa. Extant South American pipids and the African *Hymenochirus* are characterised by broad flattened skulls with a generally extensive supraorbital shelf; anteriorly wide parasphenoid; the presence of only the superior perilymphatic foramen and only a single acoustic foramen; a separate clavicle and scapula; and widely expanded iliac shafts. The distinctive morphology of pipids in general and of *Xenopus* in particular leaves no doubt about the identification.

Classification and description of Brazilian specimens
Class Amphibia
Subclass Lissamphibia
Order Anura
Superfamily Pipoidea
Family Pipidae
Xenopus romeri, n. sp.

Holotype: DGM (Divisão de Geologia e Mineralogia) 568, brain-case and sphenethmoid region of skull.

Paratypes: DGM 569, partial skull; 570, braincase; 579, ethmoid region; 575a-e, vertebrae; 576, fused first and second vertebrae; 573, sacrum with fused urostyle; 571, scapula-clavicle; 572, humeri; 577-578, ilia.

Locality: fissure deposits in limestone in the quarry of the Com-panhia National de Cimento Portland (Mauà), São José de Itaboraí, Estado Rio de Janeiro, Brazil[4]. Specimens collected in 1968.

Age: late Palaeocene.

Etymology: the species name honours the late Professor Alfred Sherwood Romer for his work on relationships of African and South American fossil faunas.

Diagnosis: species of *Xenopus* with robust, widened, well ossified skull with extensive fusion among braincase elements; cultriform pro-cess of parasphenoid fused or unfused; nasals co-ossified, may or may not be fused to frontals; parietal foramen opening far anteriorly on frontal; retractor bulbi muscle scars not excavating the paras-phenoid ventromedially; a well defined foramen for internal carotid artery present anterior to palatine foramen; a well ossified prepalatine connection separating palatine foramen from pro-otic foramen; three acoustic foramina (four in one specimen); condyloid fossa relatively well developed, with inferior perilymphatic foramen opening posterio-ventrally into the latter and separated dorsally from jugular foramen by a distinct roof or crest; parasagittal crests relatively far apart and meeting posteriorly almost at posterior border of frontoparietal; dorsal protuberance of ilium relatively small; first and second vertebrae fused; zygapophyseal surfaces simple.

Description: description here includes only those features necessary to confirm identification, or those that are of special anatomical interest. In DGM 568 (type) nasals and vomers are lost, not having been co-ossified (Fig. 1); in DGM 569 vomers and nasals are fused to the skull (Fig. 2), with faint or no indication of sutures.

The trigeminal foramen is separated ventrally from palatine fora-men by well ossified prepalatine connection; anterior to the palatine foramen a well ossified pillar of bone sets off an internal carotid foramen ventrally. On the medial braincase wall (visible laterally on 569 because of breakage) three prominent acoustic foramina occur (four on 569, see Fig. 2C); dorsal to the acoustic foramina a promi-nent endolymphatic foramen occurs. In occipital view inferior perilym-phatic foramina open posteriorly, separated dorsally from jugular foramina by distinct crests.

Vertebrae opisthocoelous; centra flattened, probably epichordal. Identified specimens include vertebrae 1-2 (fused), 3-6, 8-9; urostyle fused to sacrum; sacral diapophyses strongly expanded. Scapula and clavicle fused; scapula short, a prominent cleft present. Humerus with well ossified proximal end showing trochlear articulation characteris-tic of pipids, distal ends broken. Ilia with long, subcylindrical shafts, low rounded dorsal protuberance, prominently crested acetabulum,, and strong interiliac symphysis region.

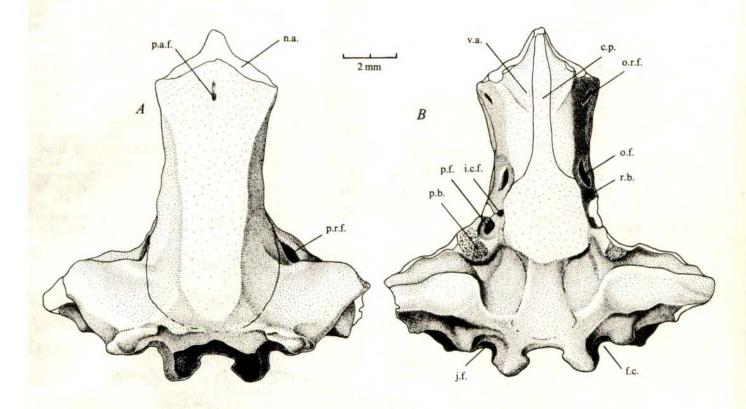
Interrelationships among extant species of *Xenopus* have not been studied extensively; it is a relatively well defined, compact genus but there are few known osteological features that can be used to separate each species. Lengthy comparisons cannot be made here, but the Brazilian fossil *Xenopus* shows no special resemblance to the extant species *X. laevis, X. clivii, X. mulleri, X. fraseri,* and *X. gilli* (material of *X. kisigiensis*[5] was not available for this study).


Fig. 1 *Xenopus romeri*, n. sp., skull of holotype, DGM 568. *A*, Dorsal; *B*, ventral; *C*, occipital. a.f. acoustic foramina; c.p., cultriform process of parasphenoid; d.p., dorsal prominence of ilium; e.f., endolymphatic foramen; f.c., condyloid fossa, f.c.l., fused clavicle; f.v., fused vomer; i.c.f., internal carotid foramen; i.p.f., inferior perilymphatic foramen; j.f., jugular foramen; n.a., nasal articulation surface; n.f., fused nasals; o.f., optic foramen; o.r.f., orbitonasal foramen; p.b., pseudobasal articulation; p.a.f., parietal foramen; p.c., prepalatine connection; p.f., palatine foramen; p.r.f., pro-otic foramen; r.b., retractor bulbi muscle scars; t.f., trochlear foramen; v.a., vomerine articulation surface.

So far as fossil *Xenopus* are concerned, *X. romeri* and the Miocene *X. stromeri* from South-west Africa[1] both have the parietal foramen in a far anterior position and relatively small occipital condyles, so far as may be judged from the rather poor figures of the latter (unfortunately the materials of *X. stromeri*, deposited in the Humboldt Museum in Berlin, have been lost). More significantly, *X. romeri* resembles an unnamed Miocene *X. tropicalis*-like form from Morocco[2] in having a relatively short centrum and closely-spaced glenoid cavities of the fused first and second vertebrae. These conditions are of special interest as there are a number of resemblances between *X. romeri* and the living *X. tropicalis* from western Africa; a greater number than with other living or fossil species. In general, the length–width proportions of the braincase region (especially the greater width of the braincase at the level of the orbitonasal foramen), the degree of fusion and the extent of ossification of the braincase elements (including the dermal elements), the posterior extent of skull table, the position of retractor bulbi scars, and the fusion of the first two vertebrae, indicate a similarity or close resemblance between the two species.

Although *Xenopus romeri* has a number of unique features that set it aside from other species of *Xenopus*, the number of resemblances to *Xenopus tropicalis* suggests that there is an actual relationship between *X. tropicalis* and *X. romeri*. Vergnaud-Grazzini[2] has suggested that the similarities to *X. tropicalis* shown by her Miocene Moroccan specimens are convergent rather than indicative of relationship. Since *X. romeri* seems to bridge the gap between the Moroccan fossils and the extant *X. tropicalis* in the configuration of the fused first and second vertebrae, it is possible that these three groups

may be more closely related *inter se* than to other species of *Xenopus*.

The presence of the now extinct *Xenopus romeri* in South America is of considerable zoogeographic interest. It is compatible with the present plate tectonic theories: South America and Africa did not separate completely until sometime in the Cretaceous[6,7]. The presence of *X. romeri* in South America and its close resemblance to the extant western African species *X. tropicalis* is strong biological evidence for a past connection between the two continents. Similar (although weaker) evidence from the same locality in Brazil is offered by *Apodops pricei*, the first known fossil caecilian amphibian, the relationships of which seem to be with a living genus from western Africa[8].

Knowledge of the southern (Gondwanan) radiation of pipids thus forms a more coherent picture. *Xenopus* is known now from South America as well as from Africa, and both of these continents also include forms that show intermediacy between *Xenopus* and the extant South American pipids: the Cretaceous *Saltenia*[9] in South America and the living *Hymenochirus* in Africa[10]. These resemblances cannot be explained by the migration of several now extinct and unrepresented phyletic lines through northern continents; they are clearly remnants of distribution on a single continental mass.

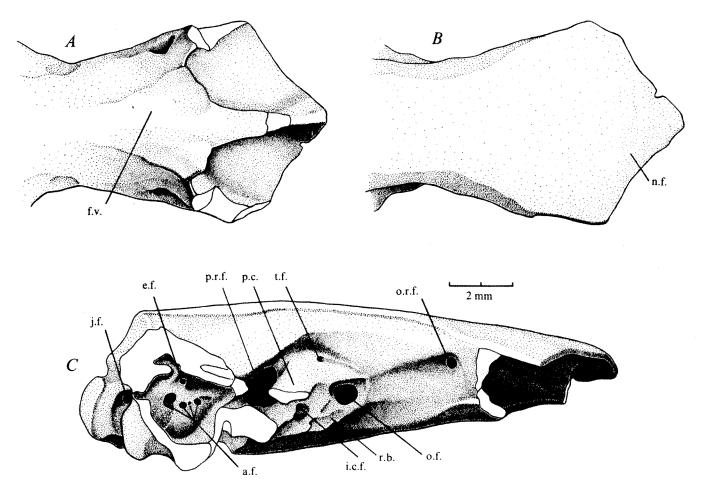
Both of the Miocene occurrences of *Xenopus* in Africa indicate that groups resembling the extant *X. mulleri* (*X. stromeri*) and *X. tropicalis* (the Moroccan fossils) were well established by that time. The resemblance of the latter two species to the Palaeocene *X. romeri* indicates that radiation within *Xenopus* must have preceded separation of the African and South American continental plates. There exists some minor disagree-


Fig. 2 *Xenopus romeri*, n. sp., DGM 569. *A*, ventral view of snout; *B*, dorsal view of snout; *C*, right lateral view of skull. Abbreviations as in Fig. 1

ment with regard to the timing of the separation, but available evidence indicates that a date of 120 Myr (early Cretaceous: Neocomian) for the onset of plate separation is consistent with a date of 90 Myr (late Cretaceous: Turonian) for the actual separation of the continents by a water gap. By about 70 Myr ago (late Cretaceous: Maastrichtian) there seems to have been a gap large enough to have prevented east–west migration of marine reef colonies[4]. *Xenopus* tadpoles can tolerate some salinity[11], but in view of the aquatic habits of the genus such tolerance would probably not be sufficient to permit migration over an oceanic barrier, even on a large raft of floating vegetation. It thus seems possible that species of *Xenopus* not much more primitive than *X. romeri* (and therefore closely related to extant species) had developed by at least 70 Myr ago, and possibly as far back as 95 Myr ago[12].

I thank Dr L. I. Price, the Departamento Nacional da Produção Mineral, Rio de Janeiro, for access to material in their collections. Dr Ana María Báez of the Universidad de Buenos Aires and Dr Allan Wilson of the University of California, have provided helpful comments and discussion.

Physical basis and ecological significance of iridescence in blue plants

MANY terrestrial plants of lowland tropical rainforests exhibit a conspicuous blue-green iridescence on their leaves—Richards[1] has observed these plants in Africa, South America, and South-east Asia. We have seen many species of blue plants on the rainforest floor in Malaya, from diverse groups including the ferns, *Selaginella*, and flowering plants. In Malaya the most spectacular and most common iridescent blue plant is *Selaginella willdenovii* (Desv.) Spring, also frequently cultivated in greenhouses. All comments on the iridescent colour refer back to the observation of Stahl[2] who reported the presence of reflection granules in the epidermal cells of *S. willdenovii*.

Although there has been ample research on iridescent colour in animals, virtually nothing has been done with plants. The iridescent green colour of the cave moss, *Schistostega*, has been explained by the presence of peculiar epidermal cells which act as refractive lenses, focusing light on specially

oriented chloroplasts[3] Here, we propose an explanation for the iridescent blue colour in plants (*S willdenovii* in particular), provide evidence supporting our hypothesis, and speculate on the physiological and ecological significance of this iridescent blue colour in shade-tolerant herbaceous tropical plants

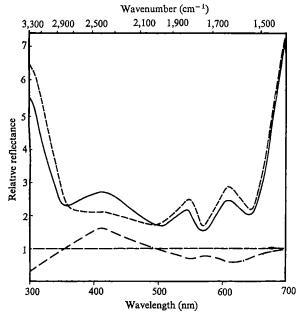
Stahl's early conclusions about plant iridescence can be refuted by simple observation First, the existence of granules reflecting blue light cannot be verified by microscopic observation Secondly, the iridescent colour disappears when the leaves are immersed in water Therefore, the colour must be an optical effect of the leaf surface and not of the internal structure The two optical phenomena that can provide a physical basis for this effect are diffraction and thin-film interference, both of which have been invoked to explain the iridescent colouring of many animal cuticles[4,5] Diffraction effects can be ruled out in the present case because there is no dispersion, reflected blue colour is constant for white incident light over a wide range of angle of incidence Furthermore, microscopic examination has revealed no surface features that could function as a grating Therefore, we suggest that the iridescent blue colour in *S willdenovii* is caused by a thin-film quarter wavelength interference filter on the upper cell wall of the epidermis This would account for previous observations, and direct experimental support has been obtained by analysing the reflectance of light from the leaves The spectral analysis was carried out using a Beckman Acta V spectrophotometer with total fluorescence attachment An opaque blank was used to project a monochromatic beam of light on to the leaf (at an incident angle of 60°) and to measure its intensity reflected (at the same incident angle) into the photocell A slit programme and a wavelength interval of 300–700 nm were used for all measurements


Fig. 1 Reflectance spectra of *S willdenovii* leaves Reflectance of the iridescent leaves is indicated by the solid line, of the non-iridescent leaves by the dashed line, and the difference between the two by the dashed and dotted line The horizontal dashed line indicates wavelengths of enhanced reflection or transmission Reflectance units are relative, and based on response of the spectrophotometer on a scale of percentage transmission

When iridescent leaves age or are exposed to sunlight for some time they lose their iridescence and develop an ordinary green appearance Chlorophyll content was found to be the same in both types of leaves (12 mg per g dry weight, by a colorimetric determination) We measured the reflectance of both iridescent and non-iridescent leaves, and plotted a difference spectrum (Fig 1) The difference spectrum shows maximum enhanced reflectance at 405 nm, a null point at

500 nm, and decreased reflectance at longer wavelengths, the effect was obscured above 660 nm by the strong reflective characteristics of all leaves[6,7] This curve corresponds closely with the operation of a quarter wavelength interference filter Precise analysis of the curve is only possible if the refractive index (*n*) of the filter is known We were not able to determine this, but estimate the filter thickness at 135–150 nm (assuming $n = 1\ 4\text{–}1\ 5$) Electron microscopic analysis would verify the existence of such a structural layer on the wall surface Solubility experiments suggested that cuticular waxes were not acting as the filter, the structural basis may well lie in cellulose orientation at the wall surface

General field observations suggest the functional significance of iridescence in certain plants Iridescent blue plants from distantly related groups grow exclusively in extremely shady tropical forest environments Furthermore, we have observed that leaves of *S willdenovii* lose their iridescence when they grow in sunlight, even when shade-green leaves of the same plant have the iridescent colour The light climate on the floor of the rainforest is extremely limiting for plants, the light intensity is low and deficient in wavelengths important for photosynthesis[10-12] The ecological importance of an interference filter in these circumstances is that the increased reflection of photosynthetically less active light (400–500 nm) is accompanied by increased penetration in the most photosynthetically active range (600–680 nm), this would have definite adaptive value Finally, preliminary observations on the leaf anatomy of *S willdenovii* indicate that the epidermal cells of these plants—egg-shaped with convex outer surface and chloroplasts in a peculiar position distal to the surface—may also function as lenses in a manner similar to that found in the moss *Schistostega*[3] Thus the analogy of a camera with coated lens may aid our understanding of the function of the leaf surfaces in these iridescent plants

Sex recognition pheromone in tsetse fly *Glossina morsitans*

ATTEMPTS to identify a sex attractant substance in tsetse flies have failed because there seems to be no olfactory agent for sex recognition[1,2] Males are apparently sexually activated only by movement of the female, but the adverse effects of naturally occurring low population densities[3] on mating frequency is overcome as both sexes encounter one another at relatively high density around host animals[1] Experience in the laboratory confirms that sexual arousal in male tsetse flies, *Glossina morsitans morsitans* (Westwood), is initiated by movement of other individuals Thus, mature adult males will initiate sexual behaviour in the absence of females and the level of activity is increased if the flies are disturbed This behaviour ceases, however, as soon as physical contact is made with the target

male It seems unlikely that a sexually aggressive male would rely on rejection or acceptance by its target in order to distinguish females of its own species, and in view of the discovery of a short range sex pheromone in the housefly *Musca domestica* L [4-7], an attempt has been made to demonstrate the existence of a positive sex recognition pheromone in *G morsitans*

Observations made during the routine mating of one male to one female in a glass tube show that pairing in *G morsitans* is achieved very rapidly The problem of eliminating possible sources of sex recognition related to female behaviour (characteristic movements, sound production, or scent production occasioned by the presence of the male) was solved by testing the responses of sexually mature males (> 7 d old), individually in tubes, to decoys consisting of dead flies of various ages and nutritional states, recovered from our colony at Langford Male responses were measured subjectively an attempted copulation was scored if the male mounted the decoy, flexed its genitalia, and attempted to orientate to the copulating position a successful copulation was scored if the aggressor engaged its genitalia with the genitalia of the decoy This classification of responses was necessary as in later experiments dead males and inanimate decoys were used, and successful copulations were impossible A passing interest such as that observed when a male attacks another live male was not counted as a mating attempt Both the male fly and the decoy were replaced for each successive test Table 1 shows clearly that dead females were attractive to sexually mature males, and that their attractiveness was not diminished by low temperature storage or vacuum drying The attractiveness of dead females, however, was progressively reduced by washing in a variety of solvents, and was abolished by non-polar solvents

On the supposition that a chemical substance in the female cuticle provided the cue for continued male sexual activity on contact, and that this substance was removed by non-polar solvents, attempts were made to recover the substance from solvent washes and to test its activity with a suitable bioassay Mature male flies were again tested against decoys consisting either of dead males or of 'pseudo-flies' made from black shoelace knots[8], both of which were demonstrably unattractive to the mature live males Female and male *G morsitans* (immobilised by chilling), or females and 'pseudo-flies' were added to diethyl ether or hexane (0 5 ml per fly) in the ratio 4 1 and shaken The solvent was then evaporated *in vacuo* at room temperature The decoys were allowed to dry completely for several hours at room temperature in still air, whereupon they became highly attractive to mature male *G morsitans*, and maintained their attractiveness for at least 4 d This implies that a sex recognition pheromone of lower vapour pressure than the solvents used had been transferred from the female flies to the decoys

A specific sex pheromone for male houseflies has been isolated from the cuticular hydrocarbon fraction of adult flies, and olfactometer tests have shown it to be attractive over short distances[4-7] In view of the fact that the tsetse pheromone reported here was contained in the non-polar cuticular lipid fraction of female flies and that it seemed to be attractive to

males only over very short distances, we compared the distribution of hydrocarbons in the cuticle of female *G morsitans* with that of houseflies

Using the methods of Carlson *et al*[6], lipid samples obtained from cuticular rinses with hexane, of adult female *G morsitans* were fractionated using liquid chromatography on silica gel The hydrocarbon fraction was subjected to temperature-programmed gas chromatography on a 3% methyl silicone column (1 8 m × 2 mm) Table 2 shows a considerable difference in cuticular hydrocarbon composition between *G morsitans* and housefly

The distribution of hydrocarbons having 30 carbons or less was 93,90 and 79% for three housefly samples and only 6 8% for *G morsitans*, with C31 and C38 being most prevalent in the latter This striking difference gives rise to speculation about differences in cuticular composition in tropical insects such as tsetse flies since the C38 hydrocarbons of *G morsitans* are less volatile than the predominant C27 compounds in houseflies

The principle of using relatively non-volatile solvents as 'keepers' to retain volatile solutes is well known and has been practised by Beroza *et al*[9] in field trials with sex pheromones of several species of Lepidoptera Thus a sex attractant material dissolved in a less volatile solvent could be 'kept' better than one dissolved in a more volatile solvent On this basis, our experimental evidence for the existence of a sex recognition pheromone in *G morsitans* which is essentially a contact stimulant is supported by the gas chromatographic analysis of cuticular hydrocarbons of this species Alternatively, the *G morsitans* pheromone may itself be a compound with a high carbon number and a low intrinsic volatility This seems likely in view of its persistence in maintaining decoys in an attractive state for several days

Protection from habituation by lateral inhibition

HABITUATION, or response decrement, functions to reduce an animal's responsiveness to maintained or frequently repeated stimuli, while ensuring high responsiveness to novel stimuli Under some circumstances, however, habituation is inappropriate, in response to sensory afference caused by an animal's own activities, for example Mechanisms for protection from habituation under such circumstances are likely to be common Here we show, in locust movement detector (MD) neurones, that whereas habituation is rapid in response to repeated small field movements it is absent in response to maintained whole field movements Prolonged whole field movements do not therefore reduce the responsiveness of the MD neurones to subsequent small field movements Protection from habituation is achieved by lateral inhibition which acts prior to the site of response decrement to suppress the response to whole field stimuli

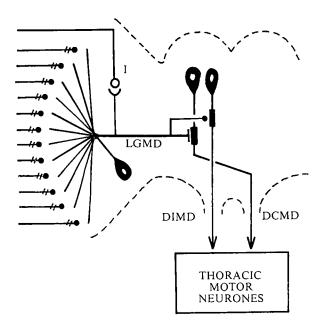
Part of the neuronal circuitry which mediates visually


Fig 1 Highly diagrammatic representation of the anatomical relationships of the MD system The LGMD has a fan-shaped arborisation in the lobula of the optic lobe Its spikes transmit along its axon into the brain, where the neurone forms an electrical synapse with the DCMD neurone and an excitatory chemical synapse with the DIMD neurone Both these neurones run to the thoracic ganglia and make synaptic contact with motor neurones involved in jumping The main fan of the LGMD is the site of afferent synapses from the medulla, which supply a processed retinal projection to the LGMD The excitatory chemical synapses are markedly labile and habituate readily (indicated by double cross-hatching) The LGMD also receives, nearer the site of initiation of spikes, an inhibitory input (I) which derives its input from spatial summation over the whole of the visual field of the eye, and which is responsible for post-convergence inhibition in the system

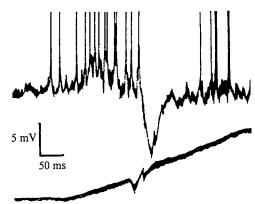
induced escape jumping in the locust has been elucidated by intracellular recordings from identified interneurones and motoneurones[1-4] Three bilaterally paired MD neurones respond vigorously to abrupt movement of small and contrasting objects anywhere in the visual field They are, however, almost insensitive to whole field movements[5-7] The lobular giant movement detector (LGMD) of the optic lobe provides the main input to two cerebral units, the descending contralateral movement detector (DCMD) and the descending ipsilateral movement detector (DIMD) which relay spikes from the brain to the metathoracic motoneurones responsible for jumping The anatomy and major connections of the MD system are summarised diagrammatically in Fig 1

The LGMD is most responsive to new movement and derives this ability from rapid decrement of the response (habituation) produced when the same part of the retina is repetitively stimulated[6,8] As decrement is limited to the stimulated area, and as the fan-like arborisation of the LGMD is the site of convergence of the afferent pathways, habituation must occur presynaptically to it This is confirmed by intracellular recordings from the LGMD, which suggest that the habituation occurs presynaptically at the afferent synapses on the LGMD fan


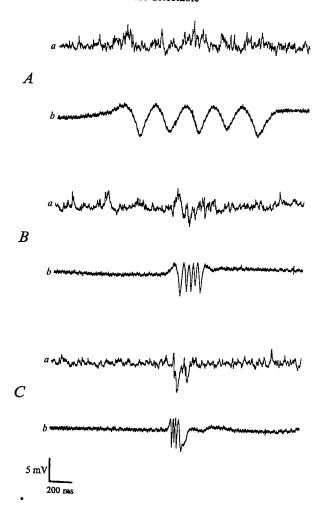


Fig. 2 Postconvergence inhibition in the LGMD of the response to a small moving target, produced by rapid displacement of the whole visual field The upper trace is an intracellular record (scale 100 ms and 5 mV) from the fan of the LGMD The slow ramp in the lower trace is the voltage analogue of the movement across the visual field of a small (about 10°) black target, which produces a large barrage of EPSPs and spikes in the LGMD The background consists of a stationary array of vertical black and white stripes covering the whole visual field About halfway through the response, the background is suddenly moved laterally, at a speed corresponding to 80 light–dark or dark–light transitions at the individual retinal receptor per second, for a period of 50 ms This is indicated by inflections on the ramp The movement of the background produces a strong hyperpolarisation which suppresses the response to small-field movement

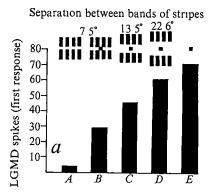
Although there is little or no response to whole field movement the illumination of most or all of the ommatidia of the retina changes under such circumstances, depending on the complexity of the visual environment Palka[8] showed that large or whole field stimuli evoked both excitation and, preponderantly, inhibition in the MD system He found that the inhibitory effect of such a stimulus to one retinal area affected the response of the other areas equally, and not in proportion to their remoteness, as would be expected of a lateral inhibitory network We have corroborated Palka's results, and by intracellular recording shown the basis of the inhibition to be large summating inhibitory postsynaptic potentials (IPSPs) in the LGMD, which occur in response to rapid changes of illumination affecting large areas of the retina (Fig 2) That this type of inhibition acts proximally to the site of convergence is consistent with the observation that its effect is equal over the whole visual field


If this postconvergence inhibition was the only mechanism suppressing the response to whole field stimuli, all labile

synapses in the afferent pathways preceding the LGMD would be excited by such stimuli, and would habituate This would render the MD system blind to small field movements which followed soon after the cessation of whole field movement, and would clearly be maladaptive But in our experiments only rapid whole field stimuli produced postconvergence inhibition in the MD system (Fig 3) Slow whole field movements produced few excitatory postsynaptic potentials (EPSPs) in the LGMD and did not appreciably decrease responsiveness to a subsequent small field stimulus, showing that such movements do not excite labile synapses in the pathways to the LGMD There must, therefore, be a further inhibitory mechanism, which also suppresses the response to whole field stimuli, located peripherally in the optic lobe prior to the site of decrement We demonstrated this inhibition (Fig 4a), it suppressed the response to a small moving target, normally a very potent stimulus, and its effect was graded in proportion to the proximity of the large stimulating field to the small target The dependence on spatial separation is typical of a classical lateral inhibitory network, in which the components of an array of similar afferent channels are mutually inhibitory in inverse proportion to their spatial separation Figure 4b

shows that the lateral inhibition generated by a large moving stimulus not only largely suppressed the response to a simultaneously presented small target but also greatly reduced the rate and extent of habituation in response to the repeated movement of the small target The dynamics of this lateral inhibition were such that during rapid whole field movements some excitation reached the LGMD, where EPSPs were generated, the peripheral lateral inhibition was supplemented by postconvergence inhibition acting in the LGMD Such stimuli sometimes produce appreciable EPSPs in the LGMD, but these are prevented from initiating spikes by the summated IPSPs

Fig. 3 Postconvergence inhibition is produced only by rapid movements of large field stimuli The entire field of the eye is occupied by a vertical array of black and white stripes The upper trace (a) of each pair of records is an intracellular recording from the fan of the LGMD The lower trace (b) of each pair is the output from a photocell which is also illuminated by the same stripes as produce the field In A–C stripes are moved laterally across the visual field at velocities corresponding to 8, 20, and 70 light–dark or dark–light transitions per second at the retinal receptor All speeds of movement tend to produce an increase in EPSPs, the faster movements increasingly produce large IPSPs as well At eight transitions per second, no IPSPs are detectable

Fig 4 Lateral inhibition of the response to a small target a, The lateral movement of two bands of vertical stripes, which extend horizontally across the visual field, at a speed corresponding to seven transitions per second at the retinal cell, produces very few spikes in the LGMD (A) This speed of movement produces no postconvergence inhibition (compare Fig 3) When a small black target is added to the stripes, the response is appreciably increased The size of the response is a function of the proximity of the striped pattern to the small target (B–D) and the full response to the target is not seen until the stripes are totally removed (E) Trials were made at 2-min intervals in the order A–E, any habituation effects would therefore tend to counteract, rather than reinforce, the trend shown here The dimensions on the diagram are in terms of the angle subtended at the eye The two bands of stripes each subtend 22 6° vertically, and the period of the striped pattern is 15° The small target subtends 7 5° b, Lateral inhibition takes place more peripherally than habituation, and protects the labile synapses from depression during whole field movement The response to repeated movements (interstimulus interval = 10 s) of the small target alone shows a rapid decrement from its original high level (○) When a large area of moving stripes is added to the stimulus in close proximity to the target, however, the response is not only depressed (see A) but also shows no significant decrement (×) Both curves are normalised for comparison

Lateral inhibition is widespread in sensory systems of both vertebrates and invertebrates, and various functions have been suggested for it, such as contrast enhancement and an increase in the information content per action potential[9,10] In the MD system it has two other functions First by preventing a response to whole or large field stimuli, it is the major factor in determining that the MD system responds preferentially to small-field stimuli and ignores visual displacements generated by the animal's own movements Second, by acting prior to the site of decrement it protects the labile synapses from habituation, and therefore preserves the novelty detecting properties of the LGMD

We believe protection from habituation to be a new and possibly general role for lateral inhibition, and it may prove to be important in other than visual systems Protection from habituation is almost certainly a common device, because of the necessity of distinguishing sensory afference caused by the animal's own activities from that which is exogenous For example, tactile afferent pathways are protected during the escape tailflip of the crayfish by an efferent control network derived from the motor output system which produces pre-synaptic inhibition[11,12] The protection mechanism we describe is derived from the afferent pathways and has the added property of being independent of the motor system, it therefore also operates in the stationary animal This type of protection may also operate in the crayfish through inhibition generated by tactile afference (J J Wine and D Kennedy, personal communication) Indeed, wherever an interneurone is found with a wide receptive field and a preference for localised and novel stimulation within that field, lateral inhibition between the pathways which feed it may be expected

Inverse relationship between serum IgG concentrations and measures of intelligence in elderly persons

WE have found a negative correlation between intelligence test scores and serum immunoglobulin concentrations in healthy subjects aged 45 yr and older This finding adds a potentially important dimension in studies of older persons who exhibit declining intellectual function

A longitudinal study of ageing in 268 elderly healthy volunteers was initiated in 1956 by the Duke University Center for the Study of Aging and Human Development The composition of this subject sample was proportionate to the race, sex and socioeconomic composition of similarly aged persons in the community from which they were recruited (Durham, North Carolina) The Weschler adult intelligence scale (WAIS) test was administered at the time of each visit to the centre Assessment of immune function was begun in 1967 with measurements of serum concentrations of IgG, IgA and IgM The method and reliability of these measurements has been detailed before[1]

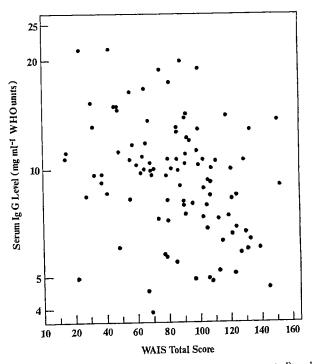
Retrospective evaluation in 1973 revealed contemporaneous serum immunoglobulin levels and WAIS test scores for 97 persons (sample 1) Where more than one set of comparisons was available on any subject, the earliest comparison was selected for analysis Sample 1 (mean age$\pm$s e m $= 79\ 3\pm$ 0 5 yr, range 70–94) had a race and sex composition similar to the entire subject sample but had a higher mean WAIS test score Both raw and scaled WAIS scores were evaluated, the results presented were independent of the type of score used Serum immunoglobulin levels were $\log_e$ transformed before analysis, in normal populations the $\log_e$ values have a Gaussian distribution[1]


Fig 1 Scattergram of WAIS total score (not age-corrected) and serum IgG level in 97 subjects from the Duke Longitudinal Study ($r = -0\ 332, P < 0\ 005$)

Evaluation of sample 1 revealed a significant negative correlation between serum IgG levels and WAIS scores ($r = -0\ 332$, $P < 0\ 005$) (Fig 1), correlations for serum IgA ($r = 0\ 161$) and IgM ($r = 0\ 085$) were not significant (Table 1) This inverse relationship between the WAIS test and IgG was detected in all race and sex subgroups Although only four subtests are presented in Table 1, all 11 WAIS subtests scores were inversely related to serum IgG level In sample 1, WAIS score and age were correlated $-0\ 157$, IgG and age, were correlated $0\ 110$ To evaluate the relationship between the WAIS scores and serum IgG levels unencumbered by the effects of age, race and sex, a stepwise multiple regression analysis was performed with total WAIS score as the dependent variable Even after age, race and sex were forced into the regression equation, IgG accounted for a significant portion of the WAIS variability (partial $r = -0\ 296$, increase in multiple $R^2 = 0\ 082$, $P < 0\ 001$) To exclude the possibility that other sources of variation, such as the effects of repeated WAIS testing, disease and terminal illness, might account for the inverse relationship, regression analysis was also performed with the initial test scores of subjects who had no clinical evidence of illness and did not die within 2 yr of the IgG determination ($n = 67$, mean age $= 66\ 8\pm0\ 6$ yr) The IgG level still made a significant contribution to the regression equation (partial $r = -0\ 323$, increase in multiple $R^2 = 0\ 104$, $P < 0\ 005$) This suggests the observed relationship was not dependent on training effects or health status

The negative relationship was reproducible A second

Table 1 Correlations between WAIS scores and serum immuno-globulin level in two samples of older persons

WAIS subtests[‡]	Sample 1*			Sample 2[†]		
	IgG	IgA	IgM	IgG	IgA	IgM

Total WAIS score¶	−0 322	0 161	0 085	—	—	—

* $n = 97$, mean age$\pm$s e m $= 79\ 3\pm0\ 5$ yr
† $n = 468$, mean age$\pm$s e m $= 58\ 5\pm0\ 3$ yr
‡ All 11 WAIS subtests were administered to sample 1, but only the four in the table were administered to sample 2 The four subtests were selected because the previous study had demonstrated that the subtests, information and vocabulary, showed the most stability with increasing age, and the subtests, digit symbol and picture arrangement showed the greatest decline The seven subtests administered to sample 1 but omitted from this table were all negatively correlated with serum IgG level
§ Because an overall value such as total WAIS score was not available for sample 2, the average of the scaled scores for the four subtests was used
¶ This score was not age-corrected

longitudinal study was initiated at Duke University in 1967 consisting of 502 white persons aged 46–71 yr These subjects represented a broad range of the middle and upper socio-economic classes of Durham On the basis of the experience with the first longitudinal study, only four WAIS subtests were administered Information and vocabulary subtests were selected because they had shown the least change with age Digit symbol and picture arrangement were selected because they had shown the greatest change with age Sample 2 consisted of 468 persons (mean age $= 58\ 5\pm0\ 3$) on whom both WAIS scores and immunoglobulin levels were available from the initial round of testing In this younger, racially homogeneous sample, the correlation between IgG level and an average of the four scaled subtest scores was negative ($r = −0\ 109$, $P<0\ 02$) Seven out of ten (sex-by-5 yr age) subgroups in sample 2 showed the same inverse relationship Three of the four subtests exhibited a negative correlation with serum IgG level (Table 1) A similar relationship was detected in subject sample 2 between serum IgA and WAIS scores (Table 1) After deletion of age and sex effects, stepwise multiple regression analyses revealed that either IgG or IgA level made a significant, but not independent, contribution to the regression equation predicting each subject's averaged scaled subtest scores (for IgG, partial $r = −0\ 086$, increase in multiple $R^2 = 0\ 012$, $P<0\ 025$) This association between serum IgA and WAIS test scores could be the result of the relationship between IgG and IgA previously reported in younger persons[2] IgG and IgA were significantly correlated in sample 2 ($r = 0\ 26$, $P<0\ 001$), but not in the older sample 1 ($r = 0\ 13$)

The variability in WAIS test scores associated with IgG levels in both samples was small but significant The magnitude of this association could be a consequence of many other sources of variation, alternatively it may reflect a major influence present in only some members of each sample Although a precise mechanism cannot be identified from our data, the sevenfold increase in variability accounted for in the older subject sample is consistent with some consequence of biological age Several testable ageing-dependent hypotheses can be advanced to explain the observed relationship First, anti-brain antibodies increase with age[3] and might have a pathogenic role in cognitive decline Second, age-related decline in a third physiological system might account for decreased intellectual performance and elevated IgG levels Finally, an effect of selective mortality cannot be excluded Two lines of evidence support this last possibility First, individuals in both samples who died within 5 yr of the time of measurement (27 subjects in sample 1 and 28 subjects in sample 2) had lower WAIS scores and IgG levels than their surviving cohorts Second,

patients with senile dementia, which is associated with early death[4], have significantly lower serum IgG levels than age matched controls (R Green and C E Buckley, unpublished) A shortened life expectancy in persons with low IgG levels and low WAIS scores could contribute to the inverse relationship between measures of immune and intellectual performance detected in older persons

We thank Dr Carl Eisdorfer and all those who worked with him gathering the psychological data, and Diane White for technical assistance This research was supported by the National Institute of Child Health and Human Development and the North Carolina Lung Association

In vivo evaluation of microcirculation by coherent light scattering

THE microcirculation plays a central role in the regulation of the metabolic, haemodynamic and thermal state of the individual Its physiological state varies over both long and short time periods and reflects the state of health of the individual, in particular it is the ultimate arbiter of the adequacy of tissue perfusion in the presence of vascular disease or injury For these reasons it is of interest to both the physiologist and the clinician to be able to monitor the state of flow and distribution of flow in the compartments of the microvasculature rapidly, conveniently and with minimal interference with the many local and central reflex controls At present such measurements depend on direct observation, plethysmography thermal or radioisotope techniques[1], which are slow or cumbersome or grossly disturb the normal state of the subject We report here the first stages in development of a noninvasive method for acquiring such information which has a rapid response and the potential ability to distinguish flow in the different microvascular compartments by the differences in flow velocities

When coherent light is scattered from a complex medium which is in internal motion, the spectral line is broadened by the Doppler effect in a manner characteristic of the velocity distribution of the motion By heterodyning or homodyning the light on a square-law photodetector, this bandwidth may be brought to audio frequencies and examined with an electronic spectrum analyser[2] Information so obtained has been used in biology for measurement of diffusion coefficients of macromolecules[3], motility of bacteria[4,5], blood flow in retinal arteries[6] and viability of sperm[7]

Although the vascular bed of, for example, the skin is "visible" from the surface, in the sense that it imparts colour to the skin, light which reaches the blood and returns will generally suffer multiple scatterings during its diffusion through tissues At present this precludes a quantitative theoretical calculation of the Doppler spectrum, which must instead be calibrated empirically against conventional physiological measures, using the predictions of idealised theoretical models as a guide

As an example of the latter, we might imagine that photons wander randomly through densely diffusing stationary tissues, encountering one or more red blood cells moving in random directions with a speed distribution $U(v)$ The distribution $P_1(\Omega)$ of Doppler shifts of those photons which encounter one

Fig 1 Raw amplitude spectrum (square root of power spectrum) of photocurrent produced by backscattered laser light (632 8 nm) from skin of fingertip, obtained with Spectra Physics 124 laser and Saicor SAI-51B time-compressed spectrum analyser in band from 800 Hz to 20 kHz *a*, With circulation unimpeded, *b*, with blood-pressure cuff inflated to 300 mmHg Elevated baseline is photomultiplier shot noise, that is, asymptote of *b* may be taken as the true signal baseline for both curves.

red cell may be found from the basic Doppler formula $\Omega = K.v$ by averaging over all the random directions involved, after some manipulation of integral identities it may be shown that

$$v^2(d^2P_1(2v/\lambda))/dv^2 = \lambda U(v)/2$$

where λ is the wavelength of the light The higher order multiple red cell encounters, P_n (Ω) are the self-convolutions of P_1 (Ω), since the photon suffers the sum of a number of independent random Doppler shifts From arguments of this sort it may be shown that (1) in principle it is possible to recover the cell speed distribution $U(v)$ from the measured spectrum, (2) the spectrum is expected to be a monotonically decreasing function of frequency, higher frequencies corresponding to faster flow speeds, and possibly possessing an integrable singularity at $\Omega = 0$, (3) the scattered light will be depolarised, with two statistically independent polarisation components each having Gaussian statistics, (4) for a random flow field with an r m s velocity of 1 cm s^{-1} the r m s bandwidth of 632 8 nm light will be 12,903 Hz times the square root of the mean number of red cell encounters (plus small corrections for the shape of red cells and refractive index)

These conclusions are, of course, based on idealised assump-

Fig 2 Power spectrum of Doppler flow signal from fingertip at intervals following ingestion of 30 ml of ethanol Arbitrary units Bandpass 5–50 kHz Data smoothed by neighbouring point averaging corrected for shot noise and bandpass filter response *a*, Control before ethanol administration, *b*, *c* and *d* follow ingestion by 5, 10 and 15 min

tions and should be taken only as a guide to the interpretation of empirical spectra

We have undertaken preliminary experiments to determine the feasibility of this method Light from a 15 mW HeNe laser illuminated a 1 mm area of skin of a fingertip The backscattered light was sensed through a pinhole by a photomultiplier The homodyne photocurrent which resulted was passed through a variable bandpass filter to a time compression digital spectrum analyser To evaluate the possibility of following rapidly the dynamics of the circulation, the signal within a particular passband was rectified and displayed on a chart recorder as a function of time

Figure 1 shows the spectrum before and after occlusion of the brachial artery with a blood-pressure cuff, demonstrating that the Doppler signal is indeed caused by blood flow The bulk of the flow signal power is actually in the band below 1 kHz but that region is more subject to artefacts resulting from tissue motion in the crude preliminary apparatus

To demonstrate the feasibility of monitoring pharmacological effects on the microvasculature, a known vasodilator, in this case a small amount of ethanol, was administered Figure 2 shows successive spectra The frequency band shown corresponds to speeds found only in arterioles, venules, and shunts The result is consistent with increased flow in large vessels and increased maximal flow velocity

Figure 3 shows the variation over time of the signal power in the 10–12 kHz band as a blood-pressure cuff is rapidly inflated above the systolic pressure and then slowly let down The initial decay is the time required for large arteries to empty before the microvascular flow stagnates When the cuff is held between systolic and diastolic pressures until the veins have filled, the flow becomes highly pulsatile In this time-resolved mode it was observed that fingertip flow is quite labile in response to room temperature, posture, respiratory pattern and emotional stimulation of the subject We know of no comparable method of demonstrating these rapid microvascular reflexes

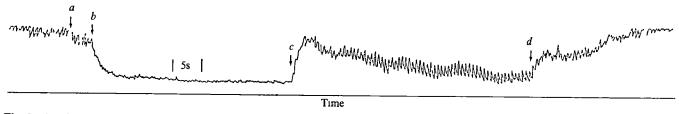
Laser Doppler spectroscopy therefore offers a promising tool for examination of the physiological state of the microcirculation rapidly and non-invasively Because it provides information about the flow velocity distribution, it has the potential ability to analyse the distribution of flow in the different microvascular compartments Applications in vascular physiology, clinical evaluation of vascular disease and assessment of the viability of burns and grafts are foreseen We would like to thank Dr Ralph


Fig. 3 Amplitude of Doppler flow signal (including shot noise baseline) in the band 10–12 kHz as a function of time during inflation of a blood-pressure cuff followed by its slow release Point *a* is beginning of inflation At *b* the cuff exceeds the systolic pressure Cuff pressure was held above systolic for 20 s and then slowly released At *c* the cuff pressure dropped below systolic, at *d* cuff pressure fell below diastolic By the end of the chart cuff pressure was entirely released Amplitude scale arbitrary

Alterations in behaviour and catecholamine biosynthesis induced by lithium

THERE IS general agreement that lithium (Li) impairs central catecholamine transmission, although the underlying mechanism is subject to debate[1–4] More ambiguous is the literature describing the behavioural effects of Li in experimental animals Although considerable evidence indicates that Li suppresses various behaviours[5–10], there are reports that this effect is only apparent after drug-induced stimulation[11–14] Results are also contradictory with respect to the behavioural effects of long term Li administration, some studies reporting continued or even exaggerated suppression with repeated administration[15–18], while others describe development of tolerance to the Li-induced behavioural suppression[12,13]

Lithium is well established as a treatment for mania and a prophylactic agent for prevention of recurrent mood disorders[19–21] Thus, the elucidation of its behavioural and neurochemical effects may provide some insight into the aetiology of naturally occurring mood disorders Since some degree of long term treatment with Li is, however, usually required before clinical improvement is apparent, it is essential to evaluate potential clinically relevant effects in chronically treated animals In our study of the behavioural and neurochemical correlates of long term Li administration, we have found that Li suppresses both spontaneous and amphetamine-induced behaviour in rats, that tolerance develops to this suppression, and that the emergence of tolerance is associated with increased tyrosine hydroxylase activity in the substantia nigra and caudate-putamen of rats

Male rats (350–375 g, Carworth Farms) were housed in groups of four and maintained on a 12-h light–dark cycle and allowed free access to food and water Locomotion was monitored automatically in sound-attenuated chambers[22,23]

All rats received nine daily injections, the last immediately before testing in the chambers The group on a regime of long term treatment received eight daily injections of LiCl (1 5 meq kg⁻¹) and a single injection of saline before testing Two

acute groups were injected with Li, either 24 h or immediately before testing The control group received nine injections of saline. Injections were given subcutaneously at the same time each day in volumes of approximately 3 ml in order to minimise local irritation produced by Li

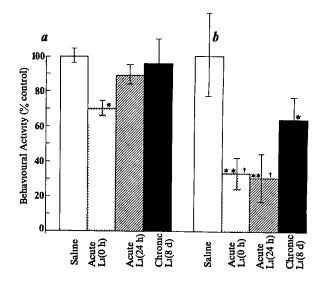
After the final pretreatment injections, animals were placed in the chambers and their spontaneous activity was monitored for 2 h Then, all groups received an injection of *d*-amphetamine sulphate (0 5 mg kg⁻¹, intraperitoneally as free base) Behaviour was monitored for an additional 2 h, at which time the behavioural response to this dose of amphetamine had subsided[22,23]


Fig. 1 Effect of acute and chronic Li administration on spontaneous locomotor activity (*a*) and on *d*-amphetamine-induced behavioural excitation (*b*) Single injection of Li (1 5 meq kg⁻¹, subcutaneously) only reduced spontaneous activity in the 0-h acute group Excitation produced by amphetamine (0 5 mg kg⁻¹, intraperitoneally), however, was depressed in both acute groups and, to a lesser extent, in the 8-d Li group
*Significantly less than saline pretreated controls, *P* < 0 02
†Significantly less than chronic Li group, *P* < 0 05
**Significantly less than saline pretreated controls, *P* < 0 001

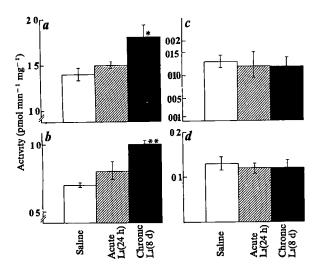
During the first 30 min after initial exposure in the chambers, only the 0-h acute group showed a decrease in activity compared with saline controls (*P* < 0 02, Fig 1) During the second-hour interval before injection of amphetamine, all groups remained relatively inactive Injection of amphetamine produced a moderate increase in locomotion for the first 30 min after injection (approximately 100 cross-overs for the saline pretreated group) Acute pretreatment with Li significantly suppressed the amphetamine-induced activity to 30–40% of saline control levels (*P* < 0 01) for up to 24 h after injection of Li Tolerance to the suppressive effects, however, seems to have occurred by 8 d, for the animals repeatedly injected with Li exhibited significantly more amphetamine-induced activity than did either of the acute groups (*P* < 0 05), but less than that of the saline control group (*P* < 0 02)


Fig. 2 Effect of acute and chronic Li administrationon tyrosine hydroxylase activity in the cell body and nerve ending regions of the nigro-striatal pathway (substantia nigra (b) and caudate-putamen (a), respectively) and in the dorsal noradrenaline pathway (locus coeruleus (d) hippocampus-cortex (c), respectively) Eight-day Li treatment resulted in an augmentation in tyrosine hydroxylase activity only in the substantia nigra and caudate-putamen

*P < 0 05
†P < 0 001

To examine the possible neurochemical correlates for these behavioural effects, rats comparable with those used for the behavioural experiments were injected with either saline or Li for 8 d, or with saline for 7 d and with Li on the eighth day All rats were decapitated 24 h after the last injection, their brains were removed quickly and four discrete regions were dissected using a brain slicing device[24] The regions were homogenised individually and examined for tyrosine hydroxylase activity by a modification of the Nagatsu procedure[25,26] The areas examined included the cell body and nerve ending regions of the dopaminergic nigro-striatal pathway (substantia nigra and caudate-putamen, respectively), and the cell body and nerve ending regions of the dorsal noradrenergic pathway (locus coeruleus and hippocampus-cortex, respectively)

Alterations in tyrosine hydroxylase activity were found only in the dopaminergic system (Fig 2) Acute Li produced a slight although insignificant increase in tyrosine hydroxylase activity But 24 h after eight daily injections of Li, the enzyme activity in both substantia nigra and caudate-putamen had increased substantially (30 and 40 % greater than corresponding controls), thus suggesting that the nigro-striatal dopamine pathway plays a role in the development of tolerance to the behavioural suppression induced by Li That is, an increased availability of dopamine, consequent to the elevation of tyrosine hydroxylase activity, might partially overcome the impaired transmission produced by Li

The failure to obtain enzyme changes in the noradrenaline regions examined seems to conflict with other reports of Li-induced increases in the turnover rate of brain noradrenaline[16,27-29] Most of these results are, however, based on whole brain assessment of turnover, while our study was restricted to the dorsal pathway It is conceivable, therefore, that the Li-induced alterations in turnover of noradrenaline are limited to the ventral or other brain noradrenaline systems The lack of a response in the dorsal noradrenaline pathway does not indicate that in this system tyrosine hydroxylase activity is refractory to change, since we have found that either chronic reserpine or desmethylimipramine administration produces marked alterations in the activity of tyrosine hydroxylase in the locus coeruleus and hippocampus-cortex[30]

With respect to brain dopamine pathways, Ho *et al*[31] report no alterations in turnover in four brain regions after several

weeks of Li treatment. Friedman and Gershon[32], however, found a substantial decrease in dopamine biosynthesis in striatal brain slices after 14 daily injections of Li Several differences in procedure may account for the discrepancy between our results and those of Friedman and Gershon, not the least of which is the large difference in time between last injection and biochemical determination (that is, 1 h compared with 24 h)

Whether or not continued chronic Li treatment would result in complete tolerance to its suppressive effects remains to be determined; however, if complete tolerance is found to occur, then the action of Li on amphetamine-induced behavioural hyperactivity would seem to be an inappropriate model for its clinical effects Irrespective of the clinical implications, however, the neurochemical events underlying the tolerance development to Li-induced behavioural suppression are of considerable theoretical interest We have shown before that prolonged impairment of central catecholamine transmission, produced by drugs or other treatments, results in an increase of tyrosine hydroxylase activity[33-35] The converse relationship is obtained when synaptic transmission is facilitated for relatively long periods[30] Thus, our finding that an augmentation of tyrosine hydroxylase activity is produced by Li is consistent with these findings Such an increase in catecholamine biosynthetic capacity may represent a compensatory response to the Li-induced impairment of catecholamine transmission which partially counteracts the suppressive effects of Li on behaviour

Lipopolysaccharide induces C-type virus in short term cultures of BALB/c spleen cells

In certain strains of mice, such as AKR, C-type viruses occur throughout life and can readily be detected by infectivity assays[1,2]. In other seemingly virus-free strains, C-type viruses can be activated *in vivo* by X irradiation[3,4], chemical carcinogens[5], graft-*versus*-host reactions[6] and *in vitro* by long term cultivation[7], by X rays[8], halogenated pyrimidine analogues[9,10] and mixed lymphocyte reactions[6]. We report here that lipopolysaccharide, a B-cell mitogen[18], induces C-type virus in short term cultures of BALB/c spleen cells

During the first 24 h, spleen cell cultures from 6-8 week old male BALB/c mice (Bomholdgard, Denmark) contained lipopolysaccharide W, *E coli* 0111 B4 (LPS, Difco, 16 µg ml⁻¹) or concanavalin A (con A, Calbiochem, 4 µg ml⁻¹) or phytohaemagglutinin-P (PHA, Difco, 10 µg ml⁻¹) or no mitogen Pellets obtained from the pooled day 3 and day 4 supernatants of four groups (LPS, con A, PHA and control), each originating from 50 cultures (1 ml) were assayed for reverse transcriptase activity[12] with poly(A)ₙ·poly(dT)₁₂₋₁₈ as template primer Figure 1 shows that LPS-treated culture supernatants contained enzyme activity which was linear for about 60 min, while in control cultures or in con A- and PHA-stimulated cultures no activity was found Enzyme induction could be reproduced using a highly purified LPS from *Salmonella abortus equi*

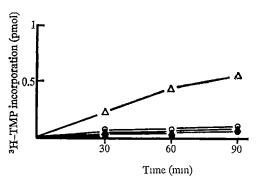
To characterise further this activity, 25 combined LPS-treated 1-ml cultures were analysed following isopycnic centrifugation on a 15-60% sucrose gradient (Fig 2) A peak of activity was


Fig. 1 Reverse transcriptase assay in samples prepared from concentrated supernatants from cell cultures stimulated with LPS (△), con A (▲), PHA (●), or control (○) Reaction mixtures (100 µl) contained 20 µl sample, 40 mM Tris, pH 7 9, 60 mM KCl, 1 mM dithiothreitol, 1 5 mM Mn(II)-acetate, 0 2 mM EDTA, 0 1% Nonidet P-40, 20 µg ml⁻¹ poly(A)ₙ poly(dT)₁₂₋₁₈ (poly(A)ₙ (Miles) and dT (Collaborative Research) were annealed in equimolar amounts), 10 µM ³H-TTP (Amersham, 7,500 d p m pmol⁻¹) Incubation at 30 °C was stopped at the indicated times by the addition of an excess of 10% trichloroacetic acid (TCA) containing 0 02 M sodium pyrophosphate Following 30 min incubation in ice, acid-precipitable radioactivity was washed on a GF/C glass fibre filter (Whatman) with cold 5% TCA and processed for liquid scintillation counting using standard procedures Reaction mixtures containing no virus were included for background determination which was subtracted from the experimental values Spleen cell cultures were prepared as described previously[11] A 1 ml culture contained 2 × 10⁶ viable nucleated cells in loosely capped disposable 12 × 75 mm tubes (Falcon) Incubation was at 37 °C in CO₂ in air (8%) Culture medium RPMI 1640 (Microbiological Associates) containing 8% foetal bovine serum (Rehatuin, Reheis), penicillin (50 IU ml⁻¹, Hoechst) and streptomycin (50 µg ml⁻¹, Novo) was changed every 24 h The removed medium from days 2-4 was centrifuged (1,000g for 10 min) and kept at −20 °C until further examination Then, 1 ml samples were pooled from corresponding cultures after thawing at 30 °C, centrifuged (35,000g for 60 min) at 4 °C and resuspended in 1/50 of the original volume in buffer (0 01 M Tris, 20 mM KCl, 1 mM EDTA, 1 mM dithiothreitol, 50% (v/v) glycerol, pH 7 9)

observed at 1 16 g cm⁻³, the density characteristic for C-type viruses

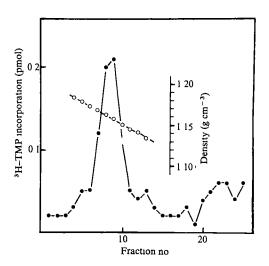
Some cellular enzymes are known to polymerise thymidine monophosphate using poly(A)ₙ poly(dT)₁₂₋₁₈ as template primer, but they work more efficiently with poly(dA)ₙ·poly(dT)₁₂₋₁₈ (refs 13-15) Moreover, terminal nucleotidyl transferase from thymus cells can be stimulated by dT₁₂₋₁₈ (ref 16) To distinguish whether the LPS-induced


Fig. 2 Sucrose density gradient centrifugation A pellet prepared from pooled day 2 to 4 supernatants of LPS-stimulated cultures was resuspended in phosphate buffered saline, pH 7 4, layered over a 15-60% sucrose gradient and centrifuged in a Beckman SW65 rotor at 35,000 r p m for 16 h at 4 °C Three drop fractions were collected from the bottom and 50 µl per fraction were analysed for reverse transcriptase activity (90 min assay) For conditions see Fig 1 Density determinations of selected fractions were performed with an Abbé refractometer

enzyme activity represents C-type viral reverse transcriptase or cellular enzymes, poly(A)ₙ poly(dT)₁₂₋₁₈, poly(dA)ₙ poly (dT)₁₂₋₁₈ and poly(dT)₁₂₋₁₈ were compared for their capacity to stimulate the enzyme (Table 1) Sucrose gradient purified Rauscher leukaemia virus (RLV) and a spleen cell homogenate were included as controls LPS-induced activity as well as reverse transcriptase from RLV showed a strong preference for poly(A)ₙ poly(dT)₁₂₋₁₈ over poly(dA)ₙ poly(dT)₁₂₋₁₈ but no detectable activity with poly(dT)₁₂₋₁₈ The cellular enzymes preferred poly(dA)ₙ poly (dT)₁₂₋₁₈ and were also stimulated by poly(dT)₁₂₋₁₈ The presence of C-type particles in LPS-stimulated cultures was verified using electron microscopy

Table 1 Template-primer requirements for enzyme activity

(Fig 3) Typical budding as well as extracellular virus could be detected

It is surprising that an ubiquitous agent such as LPS, a constituent of Gram-negative bacteria, physiologically occurring in the intestinal flora, induces C-type virus Evidence that induction of endogenous C-type virus may be quite frequent *in vivo* was reported by Aaronson and Stephenson[17] who found that most mouse strains tested had high antibody titres against endogenous xenotropic virus The relationship between LPS-induced virus, endogenous mouse-tropic virus and xenotropic virus should be investigated further It will be interesting to see whether LPS also induces C-type viruses in other species, including man

Purified LPS from *Salmonella* was provided by Dr Ch Galanos, Max-Planck-Institut fur Immunobiologie, Freiburg I Br Dr E Suter carried out the electron microscopic study

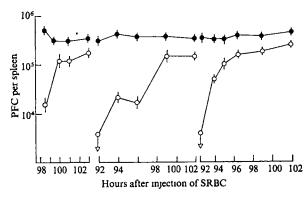
Sudden appearance of IgG plaque-forming cells

Experiments described here show that a large number of indirect, presumably IgG, plaque-forming cells (PFC) appear within a few hours during the initial stages of the IgG response of BALB/c mice to sheep red cells When washed spleen cells

are placed *in vitro* over the appropriate period indirect PFC develop as well as *in vivo*, but a few hours earlier

These experiments began when it was found that the count of indirect PFC (using the technique of Cunningham *et al.*[1]) rose from an undetectable level on the fourth day after immunisation (day 4), to the peak value (2×10^5 to 4×10^5 per spleen) by early on day 5 We followed events during day 4 in


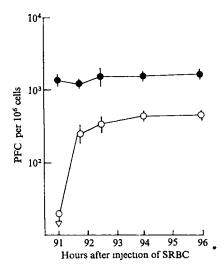


Fig. 1 Groups of 6 BALB/c female mice received 10^8 sheep red blood cells (SRBC) intravenously and PFC were assayed at intervals thereafter, by the method of Cunningham *et al*[1], but incubating for 30 min only Indirect PFC were developed by a rabbit serum against mouse IgG This was raised using purified mouse IgG and, on immunoelectrophoresis against whole mouse serum, showed only a single line, reacting with IgG It slightly inhibits PFC on day 2, when one expects the majority of PFC to be IgM (ref 3) and considerably increases the count from day 5 onwards when the majority of PFC are IgG The day-to-day levels of PFC developed by this serum follow closely those reported by other workers[2] Points are geometric means Bars indicate 1 s e ●, Direct PFC, ○, Indirect PFC, circle joined to triangle, value less than lowest level detectable (4,000 per spleen)

detail and, in repeated experiments, found that the count had risen to around 10^5 within 8–9 h When we followed the count at intervals of approximately 2 h, we found a sharp rise within the initial 2–4 h (Fig 1) These figures are means from groups of 6 mice and, as it is unlikely that the rises were simultaneous, the increase in an individual mouse could have been even more rapid

The same rise in IgG PFC was seen when washed spleen cells were incubated *in vitro* over the appropriate period The best

Fig 2 Spleens were removed 90 h after SRBC injection A pool of washed cells was prepared in RPMI 1640 containing 5% foetal calf serum 1 ml containing 3×10^7 nucleated cells was placed in each of several polystyrene tubes (12×75 mm), which were gassed with CO_2–air (5 95) and rotated on a blood cell suspension mixer at 37 °C At the times shown, 0 05 ml was removed for PFC assay, and the tubes regassed and replaced Tubes which had not been opened during the experiment gave the same counts at 96 h as those which had been sampled repeatedly

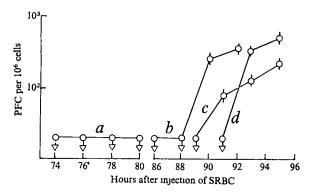
results were obtained in tubes rocked or rotated so that the cells remained in suspension in these conditions few cells became adherent One of these experiments is shown in Fig 2, during a 1 5-h incubation (2 5 h after spleen removal) a large number of IgG PFC appeared and the ratio of indirect to direct PFC is similar to what is found *in vivo* (compare Fig 1) Experiments of the type illustrated in Fig 3 show that populations placed in culture can develop IgG PFC earlier than they would *in vivo* For instance, population B, removed from mice at 86 h has developed 300 IgG PFC per 10^6 cells (equivalent to 3×10^4 or more per spleen) by 90 h, while population D, when removed from the same group of mice at 91 h had no demonstrable IgG PFC


Fig. 3 As Fig 2 but cells removed at different times after injection of SRBC Only indirect (IgG) PFC are shown, to avoid complicating the figure Counts of direct (IgM) PFC varied no more than in Fig 2, and had the following mean values *a*, 334, *b*, 1,406, *c*, 957, *d*, 1,439 PFC per 16^6 cells

Our results suggest the following sequence of events in these mice Between 74 and 86 h the spleen develops the ability to generate rapidly a large number of IgG PFC The results obtained *in vitro* show that this process (the generation of IgG PFC) does not require a structured microenvironment, nor continued humoral influences, nor perhaps adherent cells From 86 h (when IgG PFC can appear *in vitro*), the process is suppressed *in vivo* until around 92 h when a large number of PFC appear suddenly

The development of large numbers of IgG PFC within periods of 12–24 h has been observed in several other strains of mice[2-4], hence the events we have described may occur more widely

In vitro ageing and evolution of immunocompetence in long term normal lymphoid cell cultures

CULTURE of dissociated lymphoid cells *in vitro* enables the description of various characteristics of an immune response as manifested under defined conditions—but not the time course of evolution Normal lymphoid cell cultures are usually

short term, those of spleen or lymph node cells from common laboratory animals rarely surviving longer than 12–14 d Lymphoblastoid or plasmocytoma lines, established in continuous cultures originated from cancerous or Epstein-Barr virus-bearing tissues, seem to have lost their capacity for responding to specific antigens We have shown[1,2] that calf lymphoid cells can be maintained in more prolonged cultures (up to three months) without losing their immunocompetence We report results obtained using dissociated calf lymph node cell cultures surviving for more than 2 yr

Culture methods were as described previously[1] briefly, lymph nodes from 3–4-month-old animals (local slaughterhouse) within 5 min after slaughtering, were freed from surrounding tissue, quickly swabbed with ethanol, and brought to the laboratory in sterile culture medium at 37 °C After elimination of fat and outer connective tissue, the lymphoid tissue was cut into fine pieces The minced material was gently teased through a steel sieve into Eagle's MEM (Difco), buffered at pH 7 2 with sodium bicarbonate, and supplemented with non-essential amino acids without glutamine, colimycin 50 U ml^{-1}, and fungizone 10 μg ml^{-1} Normal calf serum was added at 5% concentration Aggregates were allowed to settle and the supernatant material was centrifuged at 800 r p m for 10 min The cells were then suspended in the above culture medium at a concentration varying from 8×10^6 to 2×10^7 ml^{-1}, and distributed in 1,000 ml blood transfusion flasks, each receiving 250 ml of cell suspension The culture flasks were incubated at 37 °C in a humid atmosphere of CO_2-O_2 (5 95) without agitation

Viability of the cells, estimated using trypan blue exclusion, in two different cultures is shown in Fig 1 About 60% of cells died during the first 2–4 months of culture, after this initial period, the viability did not seem to be greatly altered for more than 1 yr During these long term cultures, only moderate changes in size distribution of the cells were observed Thus in three 'blind' examinations, we found a slight but reproducible variation in the relative percentages of cells of 5–9 μm and 10–15 μm in diameter The latter represented 10% of the total viable cell population at day 1 of the culture, but only 5% at day 735 Thus the vast majority of the calf lymph node cells consisted of small and medium sized lymphocytes

We studied the ability of the lymphoid cell suspensions to respond either to a non-specific mitogen, phytohaemagglutinin (PHA) (Difco), or to specific antigens, sheep red blood cells (SRBC) and φ17 phage, active on *Streptomyces chrysomallus*, strain 17 (ref 2) With PHA, a moderate stimulation of DNA synthesis, measured by incorporation of ^3H-thymidine (2 μCi ml^{-1} of the culture medium containing 10^6 cells) was observed only during the first days of culture At the optimal time of incubation (63 h), and with the optimal dose (0 01% final concentration), the stimulation index, calculated as the ratio, (c p m in stimulated sample)/(c p m in control sample), did not exceed 2 8 It should be noted, however, that even in these young cultures the level of incorporation in the control cultures in the absence of PHA (500–600 c p m per 10^6 cells) was lower than that usually found in comparable cultures of mouse or rabbit lymph node cells

From day 50 to day 58 of culture, the response to PHA was measured after 48 h of contact with the mitogen As the incorporation in the control cultures without PHA was still lower than that found previously (less than 100 c p m per 10^6 viable cells), no enhancement of incorporation was observed after treatment with PHA The situation was the same at day 778

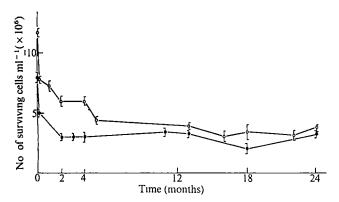
The capacity of the cultures for *in vitro* response to antigens was studied using two methods the formation of direct plaque forming cells (PFC) after stimulation with sheep red blood cells (SRBC), and the determination of the frequency of response units to φ17 phage[3] Stimulation with SRBC was performed using the above culture medium, containing 5×10^{-5} M 2-mercaptoethanol, and two RBCs per calf lymphoid cell


Fig. 1 Survival of calf lymph node cells in two different long term cultures as determined by trypan blue exclusion Means ± s e from five independent samplings Bars indicate calculated s e

The number of direct PFC was measured each day after stimulation, using the CMC method[4] No background of PFC was found in the absence of stimulation In culture to which antigen was added, the maximum level of response was reached at day 9 after stimulation Four independent determinations of the number of PFC were performed at each period of the culture

Using young cultures of calf lymph node cells (up to 2–3 weeks) the maximal number of PFC reached was 357±71 per 10^6 cells It was 342±45 per 10^6 cells after 7 months Thus, although the number of viable cells had decreased by more than 50%, the proportion of cells able to form plaques remained unchanged during this period By contrast, after 2 yr of culture, the number of PFC was only 154±47 (a young culture (1–3 weeks) was simultaneously studied and gave from 350 to 450 PFC per 10^6 cells), the situation throughout this period was reversed, compared with the previous one A 30% decrease in viability took place from day 21 to day 778, whereas a 50% decrease in number of PFC was observed for the same period, thus the proportion of PFC to total viable cells decreased by about 40%

This effect of ageing on the immunocompetence was confirmed by studying the frequency of response units towards φ17 phage The methods used for preparing and statistically analysing microcultures containing variable numbers of active lymphoid cells were as described previously[3] Briefly the main characteristic of the method is to preserve good survival of normal lymphoid cells by dilution into irreversibly inactivated cells of the same origin Inactivation without noticeable alteration of the viability was obtained by previous treatment with streptovitacin (U9361) This procedure permits the use of very small numbers of active lymphoid cells in optimal conditions to carry out a primary in vitro response These cultures are phage-stimulated and are capable of neutralising the phage by producing IgM antibodies The smaller the number of active cells in the microculture the greater the percentage of negative microcultures Positive microcultures are considered to contain at least one complete response unit, the frequency of which is calculated Four independent series of microcultures were carried out in each case Each series involved sixteen wells for each experimental point The results were as follows up to day 245, no noticeable variation in the frequency of response units (1 per 2,100–2,500 cells) was observed From day 723 to day 770 of culture, the frequency seemed to be considerably altered. In four different experiments we found a value of 1 response unit for 50,000–70,000 cells Such a reduction during a period of 16–17 months corresponds to the disappearance of more than 95% of cells able to produce antibodies neutralising significantly (more than 20%) φ17 phage

The various results reported here must be compared with the results obtained for in vivo experiments Price and Makinodan[5] have shown that an 80% decrease in the number of direct PFC was observed during the primary response of 30–32-month-old

mice, compared with 3-month-old mice Such a decrease was assigned mainly to the reduced rate, or capacity, of division of both the B and T cells Our in vitro experiments do not permit us to rule out this hypothesis, although the evolution of the in vitro immunocompetence does not seem to be directly related to that of the potentiality of proliferation Indeed, very few dividing cells seem to be present in the calf-lymph-node cell suspensions, even in the first days after removal from the animal After PHA stimulation, the level of DNA synthesis is low, however, the immunocompetence, estimated in terms of PFC or anti-phage response units, is high in the young cultures, and does not seem to vary for several months It is only after the first year of culture that the immunocompetence is affected

The evolution of immunocompetence thus seems to be independent of that of the proliferative capacity. The specificity of the immune response emphasises the particular significance of these results and supports the hypothesis that the process of ageing expresses intrinsic cellular deficiencies Moreover, the fact that the frequency of response units towards the phage is more altered than the response measured in number of PFC, suggests that the cells producing large amounts of antibody are relatively less affected by these intrinsic deficiencies Clearly, these experiments do not disprove the genetic mutation hypothesis of ageing[6] but rather lend support to some sort of cytoplasmic hypothesis, either Orgel's error catastrophe hypothesis[7], or the accumulation of cytoplasmic breakdown products[8] disturbing the mechanisms of antigen recognition and/or antibody biosynthesis

Effect of a protein-free diet on lymph node and spleen cell response *in vivo* to blastogenic stimulants

A PROTEIN-deficient diet determines an early involution of the thymus, and the quantitative difference between lymphocytes from blood, lymph node and spleen of intact and of thymectomised rats is generally smaller with a protein deficient diet than with a normal one[1,2] On the other hand, the decrease in the size of blood lymphocytes[1], and in the viability[3] of lymphocytes from lymph node and spleen, following deprivation of dietary protein is conditioned to a large extent by the atrophy of the thymus

These data already militate in favour of a predominant depletion and functional inactivation of the thymus-dependent (T) lymphocytes in experimental protein malnutrition This conclusion is corroborated by the findings we report here, which show that a protein-free diet inhibits to a much greater extent the lymphocytic activation induced *in vivo* by blastogenic stimulants known to be almost exclusively (phytohaemagglutinin[4]) or partly (sheep red blood cells[5,6]) thymus-dependent than the

Table 1 Changes in body weights and weights of a popliteal lymph node and of the spleen in normally fed and protein-deprived rats on day 4 after subplantar injection of PHA, LPS and SRBC

(figures represent percentages)

activation resulting from thymus-independent factors (lipopolysaccharides[7])

Adult male rats of a pathogen-free Sherman strain were subjected for 2 months either to a balanced normal diet (commercial chow, CNRS, Orleans) or to a protein-free diet The latter contained (per 100 g dry weight) 73 4 g sucrose, 10 g white dextrine, 10 g peanut oil, 5 7 g salt mixture (ref 8), 0 5 g choline chloride, 0 06 g inositol, and the following vitamins (in milligrams) thiamine, 1 0, riboflavin, 2 0, niacin, 20 0, Ca pantothenate, 3 0, pyridoxin, 2 0, folic acid, 0 1, vitamin B_{12}, 0 006, biotin, 0 020, tocopherol, 1 0, menadione, 1 0, vitamin A, 5,000 IU, vitamin D, 1,000 IU

Phytohaemagglutinin, (Eurobio, Paris, PHA), lipopolysaccharides from *E coli* 055 B5 (Difco, Detroit, LPS) and sheep red blood cells (SRBC) were injected into both hind foot pads of normally fed rats (3 mg of PHA, 12 5 µg of LPS, and 6 × 10[8] SRBC injected into each foot pad) at doses double those in protein-deprived rats (respectively, 1 5 mg, 6 µg and 3× 10[8]) The animals were killed on day 4 after injection of PHA, and on days 4 and 8 after that of LPS and SRBC All rats received intraperitoneally 1 h before death 1 µCi g⁻¹ ³H-thymidine (CEA, Saclay, specific activity 5Ci mM⁻¹)

The mean weights of a popliteal lymph node and of the spleen were determined and the incorporation of ³H-thymidine into these organs was measured in a liquid scintillation counter (Intertechnique, Paris) in the presence of scintisol The data

obtained in treated rats were compared with those of non-treated ones subjected to the same regimen On day 8, the responses were very weak even with a normal diet Therefore only the findings of day 4 were analysed

The weight of the popliteal lymph nodes and, even more, the incorporation of ³H-thymidine increased strongly on day 4 after injection of each of the three stimulants in normally fed rats (Tables 1 and 2) The increase was, however, much more marked with PHA and SRBC than with LPS The activation of the DNA synthesis was obvious even if it was not calculated per lymph node as a whole but per mg of lymphoid tissue In protein-deprived non-treated rats, the spleen showed a striking drop both in weight and in DNA synthesis, whereas in popliteal lymph nodes, the decreases in weight (Table 1) contrasted with an increased incorporation of ³H-thymidine per mg of tissue ($P < 0 05$) (Table 2) This may correspond to a selective disappearance of non-dividing, probably thymus-dependent, lymphocytes as suggested from previous data[1,9]

The lymphocytic activation induced by PHA per entire lymph node was 6 54 times weaker in protein deprived-rats than in controls (× 4 33 against × 28 31), 4 28 times weaker (× 1 24 against × 5 31) after injection of LPS, and 3 81 times weaker (× 4 29 against × 16 38) after SRBC (Table 2) Whereas the spleen was not significantly influenced by PHA, and even reduced and inactivated after injection of SRBC, on a protein-free diet, protein-deprived rats injected with LPS displayed a

*Values obtained from counts made on pools of two lymph nodes
†Values obtained from counts made on pools of four lymph nodes and two spleens (two rats)

noticeable splenomegaly (1 51 times the weight of the spleen of non-injected controls, Table 1) and a very strong activation of the synthesis of splenic DNA (5 68 times the normals, Table 2) Therefore, the stimulation of the total number of lymphocytes from lymph node and spleen provoked by LPS in protein-deprived rats was not at all weaker than that observed in normally fed rats, contrary to what had been observed with the two thymus-dependent stimulants

The finding that in protein-deprived rats the lymphocytic response to LPS spread up to the spleen whereas the response to PHA remained almost completely limited to the popliteal lymph nodes, may be attributed to the higher diffusibility of the LPS molecules In the experimental rats the diffusion was probably facilitated by the atrophy of the lymph node follicles[9], which normally tend to retain the antigens[10], and thus play the role of a barrier against the dissemination of the latter The extent of the diffusion of LPS with a protein-free diet was emphasised by the appearance of necrotic areas in the liver of LPS-injected rats Normally fed rats treated with LPS and protein-deprived ones, non-injected or injected with PHA or SRBC, did not exhibit similar lesions In addition, doses of LPS double those used in the experiments described above, provoked a 44% mortality with a protein-free diet whereas corresponding doses were inoffensive to normally fed rats

The inhibitory effect of protein deprivation on the lymphocytic response to SRBC was less marked than the effect on the response to PHA Indeed, the action of PHA concerned almost exclusively the T lymphocytes whereas SRBC stimulated both the T and B cells, and the inactivation of the latter by the protein-free diet was much less pronounced than that of T lymphocytes[2]

Increased hyaluronic acid production on stimulation of DNA synthesis in chick embryo fibroblasts

STUDIES of differentiating tissues indicate that the characteristic products of differentiated cells begin to appear only after cell multiplication has slowed or stopped[1] Therefore, it was concluded that cell multiplication and differentiated function are mutually exclusive Although this conclusion was based mainly on studies of progressively developing tissues, it has been extended to cells which have already differentiated but have retained the capacity to multiply[2] This is supported by some older studies of differentiated cells in culture[3-5] There is growing evidence, however, from studies both in vitro[6,7] and in vivo[8], that cell multiplication and differentiated function are compatible in differentiated cells capable of multiplication Here we add to that evidence by showing that the production of hyaluronic acid, a characteristic product of connective tissue, is positively correlated with the multiplication rate of chick embryo fibroblasts

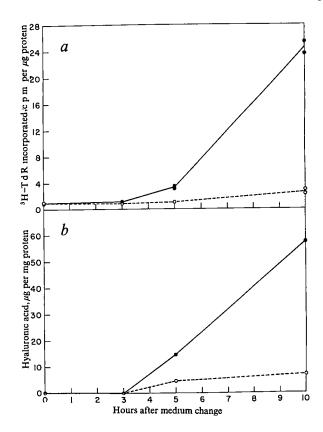
Chick embryo cells were cultured as described by Rein and


Fig 1 Four-day-old cultures in 100-mm tissue culture dishes were turned-off by changing to Medium 199, *p*H 6 8, with 2% (v/v) tryptose phosphate broth and without serum The *p*H was controlled by varying the amount of $NaHCO_3$ in the medium 16 h later the cultures were washed three times with Earle's salt solution at *p*H 6 8 Either turn-on medium (Medium 199, *p*H 7 4, with no tryptose phosphate broth and with 1% (v/v) chicken serum) or turn-off medium (Medium 199, *p*H 6 8, with no tryptose phosphate broth and with no serum) was added back to the cells *a*, The rate of DNA synthesis by turned-on and turned-off cultures was measured at various times after the medium was changed by the incorporation of ³H–TdR into acid insoluble material in a 1 h pulse DNA synthesis was measured under identical conditions by changing all cultures to Medium 199, *p*H 7 4, with no tryptose phosphate broth and no serum and with ³H-TdR (0 2 μCi ml⁻¹) for the pulse *b*, Medium was collected from subsets of the cultures at various times after the medium was changed and assayed for the amount of hyaluronic acid accumulated ●, Turned-on cultures, ○, turned-off cultures

Rubin[11] They were grown at *p*H 7 4 in Medium 199 with 2% tryptose phosphate broth and 1% chicken serum The multiplication rates of confluent cultures were controlled by manipulating *p*H and serum concentration of the medium[9,10] Low multiplication rates (turned-off cultures) were obtained by incubating cells for 16 h in serum-free medium at *p*H 6 8 Cultures were then stimulated to multiply faster (turned-on) by changing to medium (*p*H 7 4) containing serum and were compared with cultures to which fresh turn-off medium had been restored

Medium was collected from subsets of the cultures at various times after the change of medium The cells were then washed once with buffered physiological saline and the washings were added to the collected medium This mixture was lyophilised and redissolved in a small volume of distilled water NaOH was added, to a final concentration of 0 1 N, and the solution was incubated overnight at room temperature Acid mucopolysaccharides were isolated by the procedure of Bollet[13,14] as modified by Morris[15], giving 90% recovery of a known amount of hyaluronic acid added to Medium 199 Acid mucopolysaccharides were assayed by the method of Dische[16] as modified by Bitter and Ewins[17]

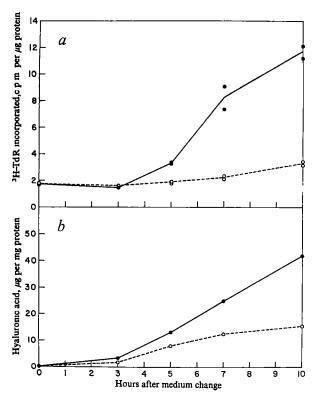
The relative rates of DNA synthesis were measured by the incorporation of ³H–thymidine (³H-TdR) into acid insoluble


Fig. 2 Four-day-old cultures in 100-mm tissue culture dishes were turned-off by changing to Medium 199, *p*H 7 4, with 2% (v/v) tryptose phosphate broth and without serum 16 h later the cultures were washed three times with Earle's salt solution at *p*H 7 4 Either turn-on medium (Medium 199, *p*H 7 4, with no tryptose phosphate broth and with 2% (v/v) chicken serum) or turn-off medium (Medium 199, *p*H 7 4, with no tryptose phosphate broth and with no serum) was added back to the cells *a*, The rate of ³H-TdR incorporation at various times after the medium was changed, measured as in Fig 1 *b*, The amount of hyaluronic acid accumulated in the cultures at various times after the medium was changed ●, Turned-on cultures, ○, turned-off cultures

material in a 1-h pulse[11] The overall rate of DNA synthesis of a culture reflects the proportion of cells in the S phase of the cell cycle at any given time, and, therefore, is proportional to the rate of multiplication of the culture[12]

The cultures kept in medium at *p*H 6 8 with no serum continued to synthesise DNA slowly during the 10 h of measurement (Fig 1*a*) Cultures given medium at *p*H 7 4 with 1% serum had doubled their rate of DNA synthesis at 5 h, and had increased it almost tenfold at 10 h These turned-on cultures had also accumulated three times as much hyaluronic acid as the turned-off cultures at 5 h, and eight times as much at 10 h (Fig 1*b*) The insensitivity of the assay at hyaluronic acid levels less than 2 µg mg⁻¹ cell protein prevented accurate measurements of hyaluronic acid production earlier than 3 h after the medium change

To show that the differences in hyaluronic acid production were not merely an effect of *p*H, cells were turned-off by incubating them for 16 h in serum-free medium at *p*H 7 4 They were then turned-on by adding serum-containing medium at the same *p*H When serum concentration alone was varied, there was less difference in DNA synthesis rates between turned-on and turned-off cultures than when both *p*H and serum concentration were changed (Fig 2*a*) The turned-on cultures were synthesising DNA at a distinctly faster rate than the turned-off cultures at 5 h, and reached a 3 5-fold greater rate at 10 h. The amount of hyaluronic acid accumulated was detectably greater in the turned-on cultures at 5 h and had become almost three times as great at 10 h (Fig 2*b*).

These results show that the rate of cell multiplication and expression of differentiated function, as represented by hyaluronic acid production, are positively correlated with one

another We have found this situation to continue for at least 24 h after stimulation, by which time almost all the cells have undergone division Although we have not yet shown that DNA synthesis and hyaluronic acid production are positively correlated in a single cell, we conclude that there is no basis for postulating an incompatibility between multiplication and differentiated function in this sytsem

Mitotic delay in the slime mould *Physarum polycephalum* induced by low intensity 60 and 75 Hz electromagnetic fields

INTEREST in the biological effects of non-ionising radiation has increased in the past few years, with most workers focusing on radio frequency and microwave regions of the spectrum[1-3] The ubiquity of low level 50–60 Hz electromagnetic radiation in the environment is a strong reason to investigate the biological effects of extremely low frequency radiation[4,5] We have examined the effects of low intensity 60 and 75 Hz electromagnetic fields (EMFs) and have observed delays in the mitotic cycle of the myxomycete *Physarum polycephalum* after continuous exposure Significant delays were observed after approximately 100 d of continuous exposure, corresponding to about 300 mitotic cycles

We used *Physarum polycephalum* because (1) its normal life cycle has been documented extensively both morphologically and biochemically, (2) the desired vegetative or reproductive stages can be induced at the discretion of the investigator and (3) stationary cultures undergo naturally synchronous mitosis In synchronous mitosis an entire culture of approximately 10⁹ nuclei simultaneously undergoes mitosis, permitting accurate observation of cycle timing[6,7] Synchronous mitosis occurs at predictable intervals so that the time between mitoses can be used as a sensitive indicator of EMF effects Stationary macroplasmodia can be obtained by allowing a sample of microplasmodia from submerged shake-flask cultures to coalesce on filter paper supported by milk-filter disks, growth medium is added after coalescence Both submerged shake-flask cultures and stationary macroplasmodia were exposed continuously to EMFs

Radiation fields were simulated by application of crossed electric and magnetic fields alternating in phase at 60 or 75 Hz, at levels of 0 7 V m⁻¹ and 2 0 gauss, selected to correspond to similar fields which may be generated by the US Navy's proposed Project Sanguine communications antenna[8] Our field intensities are a factor of ten greater than ground-level intensities

projected in 1970 for the Sanguine antenna, ambient 50–60 Hz fields arising from both natural and artificial sources are often within an order of magnitude of these intensities EMFs near electrical appliances in the home are often[9] in the range 10–25 gauss and 2–200 V m^{-1}

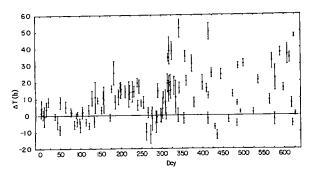
The magnetic field was generated by means of four large, thin rectangular coils placed parallel to each other at regular intervals, the entire working region was exposed to a uniform alternating field Electric fields were produced by applying a small voltage ($\sim$40 mV) to parallel stainless steel electrodes in contact with the growth medium Each container in the incubator (shake flasks and macroplasmodia dishes) was equipped with its own, individually adjustable pair of electrodes Direct electric currents were blocked by a capacitor, alternating currents through the cell were about 0 2 mA As a check on possible electrolysis of the growth medium, the pH of several flasks containing only growth medium was monitored for several days and found to be unchanged Control cultures and cultures exposed to EMFs were maintained in separate incubators at temperatures of 25 5±0 3 °C The incubators were identical in every respect except that field coils and plates were not activated in the control incubator Stock lines of *P polycephalum* were maintained as microplasmodia in submerged shake-flask cultures in both the simulation and control incubators, cultures were removed from the incubators only to transfer them to fresh growth medium or to withdraw samples for stationary macroplasmodia As soon


Fig 1 Relative time required for stationary cultures of *P polycephalum* to reach the metaphase configuration of mitosis compared with the number of days of continuous exposure to 75 Hz EMFs (0 7 V m^{-1}, 2 0 gauss) Each point represents the average of 10 cultures from which the average of 10 control cultures for that day has been subtracted The error bars are 95 % confidence limits

as stationary cultures were made, both submerged and stationary cultures were returned to simulation and control incubators To eliminate small day-to-day variations in mitotic cycle timing an identical number of stationary control cultures was set up each time observations were to be made on a group of experimental cultures All cultures were handled in an identical fashion using aseptic techniques The experimental parameter was the time required for stationary cultures to reach metaphase of the second mitotic division measured from the addition of growth medium The second division was used because it occurs approximately 14 h after feeding, so that observations can be scheduled in the morning Periodic measurements of the interval between the second and third mitoses confirmed cycle delays ascertained from observations of the second mitosis alone

After a culture had been in a 60 Hz EMF for 80–100 d a significant mitotic delay became evident, while the same effect took 100–120 d in a 75 Hz EMF To determine whether the change in the mitotic cycle was reversible, several cultures were moved from the simulator to the control incubator The delay persisted for 30–60 d during which time the mitotic interval slowly converged to the control interval No significant delay was observed in cultures exposed for 200 d to weaker 75 Hz EMFs of 0 15 V m^{-1} and 0 4 gauss Furthermore, when cultures with a delayed cycle were put in these fields after being taken

from the higher intensity 75 Hz simulator, the delay slowly decreased and became insignificant after 40 d

Figure 1 presents data for cultures exposed to 75 Hz EMFs, data for 60 Hz fields are similar The dip in the curve during days 260 to 310 results from difficulties with control cultures, which became excessively slimey and underwent mitosis asynchronously, on day 310 they were replaced with alternative cultures that had been maintained in the control incubator from day 1 as a reserve

The data were analysed by two statistical tests, both test the null hypothesis that experimental and control populations are identical An analysis of variance was used to apply a test of significance simultaneously to differences between all possible pairs of day-averages In other words, the question posed is can a horizontal line be drawn through the data (not necessarily at $\Delta = 0$) ? A signed ranks test was also used; in the test, the error bars on the data points are ignored and the number and extent of positive differences are compared with negative differences to determine if any net effect is present On some days mitosis took less time to occur in experimental than in control cultures This test asks whether the reversal happened often enough to accept the null hypothesis Our analysis shows that for both 60 and 75 Hz data, both statistical tests indicate that the null hypothesis can be rejected with at least 95 % confidence The 75 Hz data for days 260–310 were included in our analyses

We conclude that low level, low frequency EMFs can influence biological systems This conclusion agrees with findings from other laboratories[4,5] Two important features of our observations deserve emphasis First, delay in the mitotic cycle does not show up until after the cultures have been exposed for long periods Second, the delay does not disappear immediately when the cultures are removed from the field simulator

Rapid quantitation of membrane antigens

STUDIES of cell-surface antigens are important in several fields of biological research, notably transplantation and tumour research The most commonly used tests for such antigens involve assays requiring complements, and the subsequent measurement of cellular damage by the release of radioactive isotopes or the uptake of supravital dyes Radioimmunoassays which measure directly the antibody–antigen reaction in such studies would have considerable advantages Although it is possible to label antibody molecules directly, such attempts have so far been unsuccessful because of high background binding values Furthermore, variations in the composition of the antisera would make each antiserum a unique target for radiolabelling with consequent variations in results We have

Table 1 Use of ^{125}I-protein A for rat, mouse and human cell typing

Cells in tubes or microtitre test plates were incubated with (25 μl) antisera for 30 min at 4 °C, washed and incubated with ^{125}I-labelled (50,000 c p m) protein A or ^{125}I-labelled whole bacteria After a further 30 min at 4° C the cells were washed and counted Cells on plates were washed by centrifugation followed by shaking out the supernatant, and transferred to tubes for counting Rat, mouse and human sera were used at dilutions of 1 125, 1 100 and 1 5, respectively The P815 mouse mastocytoma cells were from *in vitro* cultures
*HL-A type was determined by Dr Bertil Lindblom at the University Hospital using "Uppsala" antisera and a trypan blue cytotoxicity test
†Anti-HL-A sera from McIndoe Memorial Research Unit, East Grinstead, Sussex, UK
Arrows represent anti

tried to circumvent this using a radiolabelled homogeneous marker for IgG molecules produced by certain bacteria

Protein A from *Staphylococcus aureus* Cowan I binds specifically and with high affinity to the Fc portion of most mammalian IgG subclasses[1] In our assay ^{125}I-labelled *Staphylococcus aureus* Cowan I or labelled protein A were incubated with cells precoated with a wide range of antisera to membrane components Radioactivity (c p m) provides a measure of the number of IgG molecules bound per cell and hence the number of specific probe–surface markers The value of protein A as an immunological probe lies in its versatility, as in our example, in which a single ^{125}I-labelled protein A preparation has been used to study antigens on human, rat and mouse cells precoated with rabbit and monkey as well as with alloantisera

The preparation and iodination of protein A have been described elsewhere[2] Whole bacteria were isolated in a similar manner but were simply washed free of excess iodine We have used this ^{125}I-protein A to develop a complement-free radioimmunoassay applicable to a wide range of mammalian membrane antigens Table 1 shows how the method can be used to type human, mouse and rat lymphoid cells with alloantisera or xenoantisera The data for rat and mouse show the expected gene dose effect as observed under optimal reaction conditions using both antibody and ^{125}I-protein A in excess Such a gene dose 'control' provides a good test of the function of any individual experiment Cross reaction of Lewis anti-DA with BD rats is also clearly shown

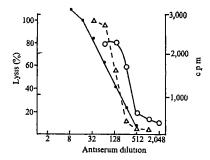
Thus, for rat and mouse systems, using inbred material, the


Fig. 1 Triplicate dilutions of rabbit anti β-2 microglobulin were assayed for ability to bind to 10^5 human T cells by three separate methods The ^{51}Cr assay[4] (○) and trypan blue test (△) are plotted as percentage lysis because these assays measure cell death The protein A assay (●) measures directly the number of antibody molecules bound per cell, and the cells remain viable throughout, c p m bound at each antiserum dilution are therefore plotted Sensitivity of the IpA assay can be varied simply by changing the specific activity of the iodinated reagent
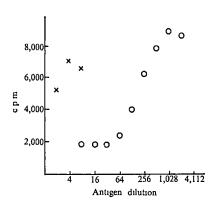

Fig. 2 HL-A antigen isolated by standard procedures[5] from splenic lymphocytes after HN$_4$Cl removal of red cells, was diluted with saline and a constant amount of antibody added (sufficient to give 10,000 c p m per 10^6 cells) with ^{125}I-protein A After 2 h at 4° C, 10^5 cells were added per well of the test plate and incubation continued for a further 30 min at 4° C Plates were centrifuged, washed and incubated with protein A in the usual way ○, HL-A 2 antigen, ×, HL-A 12 antigen Antiserum used, A macacus anti HL-A 2 serum[5]

results of this assay were highly satisfactory Table 1 shows that the assay can also function in the HL-A system, although sizeable binding occurs between supposed 'negative' serum-cell combinations Extensive cross reactions can occur, however, between HL-A antigens, this is in agreement with the cross reaction found[3] between HL-A2 and HL-A28 When we compare (Fig 1) the protein A assay with conventional assays for HL-A such as trypan blue or ^{51}Cr using microassays in plates[4], we found a positive correlation between the three tests The ^{125}I-protein A assay has a similar sensitivity to that of the trypan blue or ^{51}Cr assays, but is more linear and thus more precise than the other two tests

The ^{125}I protein A assay was also tested for its suitability in testing for soluble HL-A determinants in inhibition assays Figure 2 indicates that the protein A assay is very suitable for studies of HL-A antigens in soluble form The inhibitor assay obtained was again more linear than inhibition of trypan blue or ^{51}Cr lysis

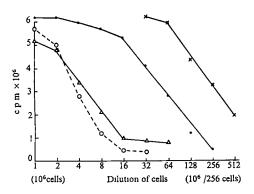
Whole *Staphylococcus aureus* bacteria bind to the Fc region of IgG and there seemed to be no reason why bacteria could not be heavily labelled, for example, for cell suicide experiments Also cells carrying whole bacteria can be readily separated by Ficol gradient centrifugation (V Ghetie, K Nilsson, and J Sjoquist, unpublished), from those not carrying bacteria In preliminary studies we have iodinated bacteria and used them in an identical manner to that used for protein A Figure 3


Fig 3 Dilutions of T and B cells in microtitre test plates were assayed directly for binding of ^{125}I-labelled whole bacteria or preincubated with rabbit anti-Ig sera and assayed for binding of ^{125}I-labelled whole bacteria The assay conditions are as described in the footnote to Table 1 ○, T cells+autologous serum, △, T cells incubated with anti-Ig, ●, B cells + autologous serum, ×, B cells incubated with anti-Ig

shows such an assay involving human B and T cells B cells or T cells separated by T cell rosettes[6] were incubated with normal human sera or rabbit anti-Ig sera before testing

Using ^{125}I-labelled *Staphylococcus aureus* Cowan 1 strain bacteria, human B lymphocytes incubated with anti-Ig antibodies bind approximately four times the number of bacteria than do uncoated B lymphocytes, and some 100 times more than T lymphocytes treated or not with anti-Ig Note that our antisera contained antibodies against light chains (both χ and λ chains) but still failed to react with human T lymphocytes as assessed by this assay (in other words, there is no difference between T lymphocytes treated or not with anti-Ig)

We have described mainly how ^{125}I-protein A assays can be used to supplement conventional methods in mammalian systems for assaying cell-bound and soluble antigens Several points make protein A assays unique, perhaps the most important being the specificity of binding to Ig molecules Protein A will only bind to IgG 1, 2 and 4 in human cells, there being no binding to IgG 3 or IgM for example In general IgG 1, 2 and 4 account for about 92% of human IgG We have carried out a series of experiments in which human cells precoated with alloantibodies are then coated with rabbit anti-IgG before addition of protein A Such sandwich techniques, however, hardly increase specific binding in the human system In the rat and mouse system it is not known exactly what percentage of complexed IgG binds protein A but our sandwich assays indicate it to be 60–100% in both species Calculation of the absolute number of antigen molecules per cell are, of course, affected by such considerations but this is easily checked by including a sandwich assay as described above The assays described in Table 1 and Figs 1 and 2 approach linearity and we expect total linearity when the assays improve technically This makes them much more amenable to kinetic studies and also to studies of cross reaction than complement-dependent assays In addition cells are live at the end of the experiment and loss of counts from cells can be easily monitored

Membrane changes in a circadian system

Njus *et al*[1] have recently suggested a membrane model of a biological clock and propose that the clock mechanism is a feedback oscillator in which the ion transport channels envisaged in the fluid mosaic model of cellular membranes[2] are involved directly It is postulated that the proteins which make up these channels respond to changes in concentration gradients of specific ions in the membrane, by grouping to form transport channels when the gradient is small, and dispersing to non-transporting modes when the gradient is large Thus the protein distribution in the membrane could be regulated by the oscillating ionic gradient and could itself regulate the ionic gradient to complete the feedback pathway and drive the oscillation It has also been suggested[3-5] that oscillatory changes at cellular membranes may be directly associated with the clock mechanism, based on observations that the phase or the period of the oscillation can be changed by treatments which affect the passage of ions through membranes

We provide direct experimental evidence for cyclic changes in membrane properties in a circadian system from studies of the pulvinule cells at the base of the leaflets of clover, *Trifolium repens* L Swelling of the cells in the adaxial portion of the pulvinule and compression of those in the abaxial portion cause the leaflet to open, and a reversal of this process causes it to close We have shown[6] that the volume changes and the resulting leaf movements are caused by an endogenous circadian oscillator located in the pulvinule Further observations (which will be reported more fully elsewhere), have shown that redistribution of cations (principally K^+) within the pulvinule accompanies these variations in volume

Table 1 Ion concentrations in pulvinal tissue (meq per kg wet weight)

		Adaxial	Abaxial	Adaxial−Abaxial
K	Day	*193 7±11 7*	167 8± 8 3	25 9± 9 2
	Night	140 3±12 5	*197 4±31 2*	−57 1±20 8
Na	Day	*19 5± 2 7*	18 5± 2 5	0 9± 2 2
	Night	19 5± 2 4	*24 6± 5 7*	−5 2± 4 1

Mean ion concentrations (±s e m) of abaxial and adaxial segments of pulvinal tissue of clover in LD 12 12 The swollen (convex) segment is shown in italics

Table 1 gives the ion concentrations in pulvinal tissue for plants grown in a 12 h light, 12 h dark cycle (LD 12 12) at 20 °C The pulvinules were sectioned into abaxial and adaxial segments at about the middle of the light and the dark intervals, and analysed using flame photometry The cation component is predominantly potassium and examination of sections stained with sodium cobaltinitrite show that most of it is in the cortical pulvinal cells which occupy at least 80% of the volume of the segments As the potassium concentration is significantly greater on the swollen side where there are fewer cells per unit volume, it is clear that each enlarged cell contains very much more potassium than each cell on the contracted side Thus there must be large tidal movements of potassium across the pulvinal membranes during the daily cycle Using a different experimental technique, Satter, Galston and co-workers conclude that similar potassium changes occur in *Albizzia*[7] and *Samanea*[8]

Radioisotope tracer studies reveal that considerable changes in potassium transport occur in pulvinal tissue during the cycle Leaves were soaked in a medium containing ^{42}K and ^{45}Ca for 2 h and washed for 30 min, their pulvinules were sectioned

into abaxial and adaxial segments The activity of the segments from groups of several pulvinules was measured immediately, and again after the short lived ^{42}K had decayed, to determine separately the influxes of the two ions The double labelling experiment was performed because it was found that calcium influx is approximately proportional to the dry mass of the tissue segments, which is more appropriate for comparison purposes than the wet mass which fluctuates as the cells expand and contract Since the dry mass is difficult to measure accurately for a small number of tissue segments, the potassium influx could more conveniently be expressed as its ratio to the calcium influx

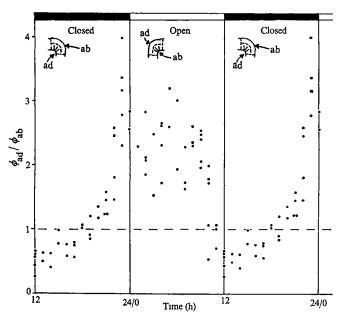
Figure 1 shows the variation in influx ratio for the two sides of the pulvinule during an LD 12 12 cycle The influx of potassium is relatively much greater when the cells are expanded than when they are contracted Such differences are expected for cells in the process of swelling or shrinking The influx ratio is, however, significantly greater or less than unity for much longer periods which commence before the leaf is observed to move and continue for several hours after the leaf is fully opened or fully closed It has not been practicable to obtain corresponding efflux data


Fig 1 Variation of pulvinal influx ratio with time (h after onset of light) for clover grown in LD 12 12 at 20 °C φ_{ad} is the K$^+$ influx per unit influx of Ca^{2+} in adaxial segments of pulvinules φ_{ab} is the corresponding quantity for abaxial segments Each point is the influx ratio for groups five to ten pulvinules One and a half cycles of the oscillation are shown

These data show that the transport properties of the membrane are changing in a cyclic manner in LD 12 12 The changes may be in membrane permeability to specific ions or in an active transport system The phase of the influx cycle is about 3 h in advance of both the leaf oscillation and the LD cycle This phase relationship is significant since it strongly suggests that the change in membrane properties is a preliminary step in the sequence of changes responsible for leaf movement, presumably by osmotically varying the volume of pulvinal cells through changes in their potassium content

The phase relationship in LD 12 12 also suggests that the flux changes are not a direct response to the light cycle This is confirmed by transferring plants to conditions of constant light and temperature (LL), following which we found that the influx oscillation continues for at least two cycles The period of these oscillations is about 27 h, which is the same as the period of leaf oscillations under these conditions[6] We therefore conclude that the oscillatory system controlling both potassium influx and leaf movement is circadian and under endogenous control

Attempts have been made to measure the transmembrane

potentials of pulvinal cells The internal potential of cells on the abaxial side is $-71\,6\pm2\,0$ mV early in the contracted phase and $-102\,1\pm6\,4$ mV early in the swollen phase (P S Targett, unpublished) Cells on the adaxial side show corresponding changes but opposite in phase The time course of these potential changes has not yet been established in detail, but it corresponds qualitatively to what is expected if the membrane potential is determined principally by the passive diffusion of potassium, since the magnitude of the potential is larger when the internal potassium concentration, and presumably the concentration gradient, is higher

In their circadian oscillator model, Njus *et al*[1] do not suggest a mechanism for the dispersal of the proteins forming the transport channels when the concentration gradients are large We propose that the electric field in the membrane may act as the dispersing agent by supplying the necessary forces The average strength of the transverse field is large ($\simeq 10^7$ V m^{-1}), but the field lines are likely to be distorted in the vicinity of transport channels where hydrophilic pathways will have much lower resistance per unit area than the bulk of the membrane The distorted field will have components in the plane of the membrane The proteins immersed in the membrane, which make up the transport channels, carry charged endings and therefore would experience forces resulting from a lateral field which could cause them to disperse or undergo changes in configuration when the electric field increases

It is well known that depolarisation of the excitable membranes in nerve[9] and the large Characean cells[10] causes large changes in the passive fluxes of specific ions, resulting in an action potential Hyperpolarised membranes also show marked changes in their conductance to specific ions[11] Eskin[12] has suggested that the biological clock in *Aplysia* may involve neuronal depolarisation

Experimental support for a circadian oscillator located at the cellular membrane in some biological organisms does not preclude the existence of a different system sited elsewhere (for example, in the nucleus[13]) which controls other oscillatory characteristics in these or other organisms If rhythmicity gives a biological system an evolutionary advantage, it is quite possible that different mechanisms have arisen independently

Effects of L-dopa metabolites at a dopamine receptor suggest a basis for 'on-off' effect in Parkinson's disease

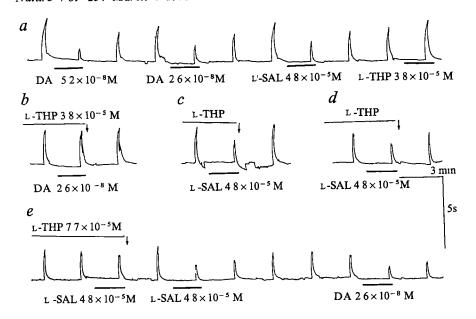
ALTHOUGH L-dopa is the most effective therapeutic agent available for the control of the akinesia of Parkinson's disease, long term therapy may be associated with a variety of therapeutic problems[1] One problem seen in some patients is a progressive loss of therapeutic response which may be associated with abnormal involuntary movements[1] A state may develop in which a good response to the drug alternates with periods of akinesia and rigidity[1-4] This has been called the


Fig. 1 Effects of dopamine (DA hydrochloride, Mann) L-salsolinol (L-SAL) and L-THP on intestinal responses evoked by electrical stimulation of gut of *Tapes watlingi* Guts were prepared as before[9], incubated in artificial seawater and stimulated electrically by means of transmural electrodes Unlabelled upward deflections represent contractions of the gut resulting from a 5-s train of square wave pulses (1 ms, 20 Hz, 10 V) The black bars indicate the periods for which DA, L-SAL or L-THP were present in the 2-ml organ bath *a*, Perfusion with artificial seawater alone, *b*, *c* and *d*, Responses 4 min after L-THP ($3\ 85 \times 10^{-5}$ M) had been added to the bath *e*, L-THP ($7\ 7 \times 10^{-5}$ M) was also present After the times marked by arrows L-THP was washed from the bath

'on-off' effect or akinesia paradoxica[1] While low blood levels of L-dopa may explain the onset of akinesia ('off' effect), this cannot explain the sudden reversal of patients' akinesia ('on' effect) which may occur without additional dosage of L-dopa[2,3]

Several mechanisms have been proposed to explain both the progressive loss of efficacy and the 'on-off effect, but so far there is little supporting data[1-4] One suggestion has been that complex metabolites of L-dopa, which are structurally similar to apomorphine, may antagonise the effects of dopamine[6] Two complex metabolites of L-dopa, tetrahydropapaveroline (THP) and salsolinol (SAL) have been identified in the urine of patients with Parkinson's disease who had been treated with L-dopa[6] THP has also been identified in rat brain after administration of L-dopa[7] It has been suggested, however, that THP, SAL or similar tetrahydroisoquinoline compounds may behave as dopamine (DA) agonists and contribute to the therapeutic effect of L-dopa[6,8]

We have now found that THP may antagonise the action of DA and SAL at a DA receptor We have investigated the activity of DA and the isomers of THP (hydrochloride salt), SAL (hydrobromide salt)[13] and amphetamine at DA receptors in the isolated gut of the mollusc *Tapes watlingi*, which contains both dopaminergic neurones and specific dopamine receptors[9] Figure 1 shows the responses to electrical stimulation in one gut preparation in the presence of DA, L-SAL and L-THP Contraction was inhibited by DA ($2\ 63 \times 10^{-8}$–$5\ 26 \times 10^{-8}$ M) and L-SAL ($4\ 8 \times 10^{-5}$ M), but was hardly affected by L-THP ($3\ 85 \times 10^{-5}$–$7\ 7 \times 10^{-5}$ M) (Fig 1*a*) The DA-like effect of L-SAL suggested that this compound was a weak agonist at the DA receptor In two out of six preparations in which L-THP had no DA-like effect, the amplitude of contraction increased It is interesting that DL-THP has been reported to have no DA-like effect on adenyl cyclase from rat striatum[10]

In the presence of L-THP ($3\ 85 \times 10^{-5}$ M), the inhibitory response to DA ($2\ 63 \times 10^{-8}$ M) was abolished (Fig 1*b*), while the response to L-SAL ($4\ 8 \times 10^{-5}$ M) was unaffected (Fig 1*c* and *d*) A larger concentration of L-THP ($7\ 7 \times 10^{-5}$ M) did reduce the response to L-SAL (Fig 1*e*) In two further preparations, L-THP ($2\ 31 \times 10^{-5}$ M and $7\ 7 \times 10^{-5}$ M) completely antagonised the inhibitory effects of L-SAL ($2\ 4 \times 10^{-5}$ M and $9\ 6 \times 10^{-5}$ M, respectively) These concentrations of L-THP also antagonised DA at an equipotent concentration ($5\ 26 \times 10^{-8}$ M) Clearly, the effects of both DA and L-SAL can be antagonised by L-THP

D-THP was relatively inactive as a DA antagonist in concentrations ten times greater than those at which L-THP was effective It was equally effective when the concentration of D-isomer was 30 times greater than that of the L-isomer Both D and L-THP have antagonist activity at DA sensitive receptors

associated with adenyl cyclase of the caudate nucleus[11] When tested on five gut preparations, DA was 10^3 times more potent than equimolar concentrations of L-SAL In two experiments, the optical isomers of SAL were approximately equipotent as DA agonists The optical isomers of amphetamine (amphetamine sulphate, Sigma) had a DA-like effect on the preparation Again, the isomers were equipotent and exhibited molar potencies similar to those measured for isomers of SAL Recent studies of the DA-sensitive adenyl cyclase system in the rat striatum revealed either no DA-like activity of SAL[10] or DA antagonism by L-SAL[11] The reasons for the failure to demonstrate DA agonist activity with D- and L-SAL in DA-sensitive adenyl cyclase of the rat striatum is not clear. One possible explanation is the limited range of concentrations tested Alternatively, if SAL acts as an indirect agonist, the lack of dopaminergic nerve terminals in the preparation would exclude such an effect

Histochemical fluorescence[9] has indicated that the dopaminergic system in the gut of *Tapes watlingi* consists of varicose nerves with a presynaptic capacity for the synthesis, release and uptake of DA There are, in addition, postsynaptic receptor sites which respond to DA agonists As SAL lowers the accumulation and retention of tritiated DA in rat brain synaptosomes[12], it is possible that the optical isomers of SAL mimic the effect of DA on the gut of *Tapes* by augmenting its release and/or inhibiting its reuptake

Thus we have demonstrated the diverse pharmacological activity of known metabolites of L-dopa D- and L-SAL are dopamine agonists and L-THP is a potent dopamine antagonist

We suggest that the therapeutic effects of L-dopa that are presumed to be mediated by DA may be modulated by metabolites of DA itself Thus therapeutic success or failure with L-dopa in Parkinson's disease may depend in part on the relative rates of production and accumulation of these or similar metabolites in the brain

Peptide factor extracted from molluscan ganglia that modulates bursting pacemaker activity

NEUROHORMONES have been suggested as long term regulators of the physiology and biochemistry of nervous tissue[1-3] Long term changes in the electrophysiology and biochemistry of a specific neurosecretory cell in the land snail *Otala lactea*[4,5] suggested such a form of long term hormonal regulation, and in fact several vertebrate neurohypophysial peptides cause long term changes in the membrane properties of this cell[6] The regulatory effects observed involve the induction or potentiation of bursting pacemaker potential (BPP) activity, resulting in net excitation of the cell These effects are different from the conventional transient conductance changes produced by various putative transmitters on these cells We have now found a naturally occurring substance present in the snail brain that produces similar long term changes in the membrane properties of this neurosecretory cell The results provide evidence for a peptide neurohormone which may function physiologically in the seasonal regulation of the physiology and biochemistry of a neurosecretory cell

Crude extracts of molluscan nervous tissue were prepared by removing the circumoesophageal ganglia from *Otala lactea* and *Aplysia californica*, and rinsing the tissue in physiological saline For comparison, the buccal retractor muscle and foot muscle of the snail were also excised The tissue was blotted on filter paper, weighed, and transferred to a 5% acetic acid solution in a glass homogenising tube, immersed in a bath of boiling water

Fig 1 Effects of snail brain extracts on BPP activity of cell 11 *a*, Membrane potential traces of cell 11 (taken from a dormant snail) exposed to an extract of whole brain from aestivated snails Under control conditions the snail could not generate BPP activity A 5-min bath application of the extract induced BPP activity Washing for more than 1 h with extract-free saline restored the activity to approximately its control levels *b* and *c*, Extracts of brains from either aestivated or active snails augmented the BPP activity already present in cell 11 taken from an active snail Prolonged washing restored the membrane potential behaviour to its control state Calibration 40 mV, 12 s

a Control   Aestivated snail brain extract   Wash

b Control   Active snail brain extract

c Control   Aestivated snail brain extract   Wash

The tissue was heated for 10 min in this solution, and then homogenised twice using a Teflon-tipped pestle The ratio of extraction solvent to tissue was 20 1 (v/v, tissue specific gravity assumed to be 1 0) The homogenate was centrifuged at 12,000g for 15 min, and the supernatant was removed and lyophilised The dried material was resuspended in either snail physiological saline[4] (80mM NaCl, 4mM KCl, 10mM $CaCl_2$, 5mM $MgCl_2$, 10mM Tris, pH 7 8) for assay, or in 5% acetic acid for separation on Sephadex G-10 (0 9×43 cm) or G-25 (0 9×30 cm) columns The resulting fractions were lyophilised and dissolved in snail saline for assay Sephadex columns were standardised with blue Dextran 2000, yellow Dextran 20 (Pharmacia), cytochrome *c*, vitamin B_{12}, colbalt chloride, lysine-vasopressin, oxytocin and various amino acids as markers Elution volumes of the peptides and amino acids were determined by spotting aliquots of the various fractions on Whatman 3 MM filter paper, and spraying with ninhydrin

Assays were performed on the peptide-sensitive neurosecretory cell (cell 11)[6], taken from either active or dormant snails Dissection of the ganglion, identification of cell 11, and recording techniques were as described previously[4-6] Cells taken from dormant snails have different membrane properties from those taken from active snails[5], and therefore the samples to be tested were applied to both types of preparations The basal level of spontaneous electrical activity in the cell was usually recorded for 30–60 min before application of the material to be tested The 1-ml samples (and control samples) were added by pipette to the 4 0 ml saline bathing the snail ganglion After observation of the effect, the preparation was washed with 20 volumes of physiological saline

After application of the extract to the medium surrounding a cell from a dormant snail generating a beating pacemaker rhythm, BPP activity was induced (Fig 1*a*) relatively rapidly (seconds to minutes) Application of the extract to a cell from an active snail potentiated BPP activity already present (Fig 1*b* and *c*) The response of the cell was initially increased during the washing Prolonged washing of the cell (> 1 h) in saline was usually required to reverse the effects of the extract Thus, the factor(s) in the extract had a long term effect on the BPP activity of cell 11 similar to that observed with neurohypophysial peptides[6] The increase in BPP activity observed immediately on washing may have resulted from the removal of inhibitory substances (for example, the putative transmitters dopamine and glutamate, both of which inhibit BPP activity in cell 11) which acted only while the extract was in the bath Extracts with activity were obtained from ganglia of active (Fig 1*b*) and dormant (Fig 1*c*) snails and from the circumoesophageal ganglia of *Aplysia californica* (not illustrated) Similar extracts of the buccal retractor and foot muscles of the snail had no effect, suggesting a brain-specific substance

Preliminary attempts were made to characterise this factor(s) The BPP activating factor was lost during dialysis, but maintained full activity when exposed to 100 °C for 10 min or to 50% acetic acid These treatments had similar effects on vasopressin's ability to induce or enhance BPP activity Fractionation of the crude extract on Sephadex G-10 showed that the active factor(s) was eluted in the exclusion volume (V_E) (Fig 2*a*) whereas a potent inhibitory factor was eluted in subsequent elution volume (V_1) Since Sephadex G-10 excluded molecules with molecular weights greater than 700, we conclude that the BPP inducing factor is greater than 700 while most of the inhibitory material is smaller In standard runs on Sephadex G-10, lysine-vasopressin and amino acids eluted in V_E and V_1, respectively Fractionation of the crude extracts on Sephadex G-25 (which excludes molecules greater than 5,000) yielded an inactive exclusion volume (V_E) (Fig 2*b*) BPP-inducing activity was in the V_3 fraction (Fig 2*b*) (This fraction also contained the vasopressin and oxytocin in standard column runs) In addition, there seemed to be a larger inhibitory factor in V_2 as well as inhibitory material in V_3 (since washing the cell free of V_3 further enhanced BPP) The latter inhibition most likely corresponds to the components found in V_1 from Sephadex G-10

Fig. 2 Sephadex chromatographic separation of snail brain extracts *a*, Application (arrow) of fraction V_E (exclusion volume) from Sephadex G-10 induced BPP activity (with large amplitude slow oscillations, which generated high frequency spike activity), whereas application of the V_1 (included volume) caused inhibition of spontaneous activity and hyperpolarisation of cell 11, which was reversible washing with fresh saline (upward arrow) *b*, Application of various frations from a Sephadex G-25 separation showed that the active factor(s) was in the V_3 fraction Another, higher molecular weight factor with a slight inhibitory effect on the BPP was eluted in V_2 Note that washing the cell after application of V_3 produced an enhancement of the BPP (this may have been caused by the presence of amino acids which eluted in both V_3 and V_4 —see text for further details) Calibration 40 mV, 12 s (2 min during part of control, and V_1 wash in (*a*) and V_2 wash in (*b*)

Fig 3 Effects of proteases on the BPP-inducing factor *a*, Electrical activity in cell 11 before (control) and after application of trypsin-treated factor *b*, Same as (*a*), except the material was treated with chymotrypsin *c*, Electrical activity in cell 11 before (control), after application of the Pronase-treated extract, and after application of an equivalent amount of the extract not treated with Pronase (untreated) Calibration 40 mV, 12 s

(Fig 2*a*), since in the standard runs amino acids eluted in the V_3 fraction The final fraction (V_4) was inactive

The pharmacological effects and gel filtration behaviour of the activating factor in the extract suggest that the extracted factor might be a peptide We therefore investigated whether the extracted factor could be inactivated by proteases Aliquots of the active V_E fraction from Sephadex G-10 (Fig 2*a*) were incubated with immobilised trypsin or chymotrypsin (Worthington) or Pronase (Calbiochem) Preliminary experiments showed that all these proteases inactivated the BPP-inducing activity of vasopressin (Pronase and chymotrypsin inactivated oxytocin, but trypsin did not), and that enzyme treatment itself did not affect the assay Incubation of the active extracts with either chymotrypsin or trypsin did not inactivate the BPP-inducing factor (Fig 3*a* and *b*), but Pronase treatment abolished activity (Fig 3*c*) These results indicate that the active material was a peptide, but not vasopressin or oxytocin since both of these peptides were inactivated by chymotrypsin (and trypsin, in the case of vasopressin)

In summary, we have isolated from molluscan ganglia a factor(s) which can either induce or enhance BPP activity in a specific neurosecretory cell in *Otala lactea* The activating effects of this peptide factor are similar to the actions of certain vertebrate neurohypophysial peptides in that both are elaborated by nervous tissue, cause long term changes in the membrane properties of a specific cell in the snail, the result of which is BPP activity, are water-soluble, are stable to heat and acid, are dialysable, and co-elute from Sephadex G-10 and G-25 The extracted factor differs from the neurohypophysial peptides in its resistance to inactivation by trypsin and chymotrypsin These results suggest that peptides similar, although not identical, to the neurohypophysial peptides function naturally in the modulation of the physiological properties of nerve cells in the snail

Temperature adaptation in myosin of Antarctic fish

A RELATIONSHIP exists between the thermostability of fish skeletal muscle myosin, actomyosin and myofibril preparations and the environmental temperature at which the fish lives[1-3] Compared with those isolated from mammals and warm sea fishes, the myosins isolated from cold water species readily aggregate on storage, are more sensitive to denaturation by heat and urea, and quickly lose all ATPase activity following preparation[4,5] We have compared the properties of myofibrils and myosin prepared from the white muscle of an Antarctic fish, *Notothenia rossii*, South Georgia, British Antarctica, with homologous preparations from a tropical species, *Amphiprion sebea* (Indian Ocean, 23–27 °C) We suggest that the thermal lability of cold-adapted fish myosins arises from differences in the higher order in the structure of the molecule, this is probably an evolutionary response to attain high catalytic efficiency at low temperatures

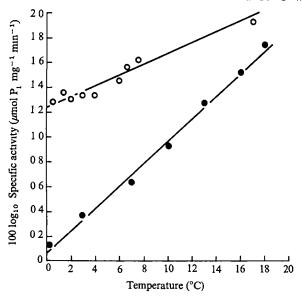
The myofibrillar ATPase enzyme from the Antarctic fish (Fig 1) has a much higher specific activity at low temperatures (0–10 °C) than does the tropical fish The apparent energies of activation for the reactions between 0 and 18 °C were


Fig. 1 The effect of temperature on the specific activity of white muscle myofibrils of *Notothenia* (O) and *Amphiprion* (●) Myofibril preparations were used for ATPase activity studies because the ATPase of myosin isolated from cold water fish is extremely unstable Myofibrils were prepared from fish expaxial white muscle[6], excluding superficial red muscle which has a different myofibrillar ATPase activity[7] Studies on the thermal denaturation of myofibrillar ATPase activity were carried out between 25 and 37 °C by incubating myofibrils (1mg ml⁻¹) in 0 05 M KCl, 40 mM Tris-HCl (*p*H 7 5) Myofibrils were added to an 18-fold excess of continuously stirred medium and an initial sample taken 0 5 min later Subsequent samples were taken at appropriate intervals and pipetted into tubes at 0 °C to prevent further inactivation Myofibrils partially inactivated by exposure to high temperatures were assayed for ATPase activity at 18 °C The assay for ATPase activity was performed in 1 5 ml 40 mM Tris-HCl (*p*H 7 5) with 6 mM ATP, 6 mM MgSO₄ and 0 2 mM CaCl₂ at *I* = 0 124 (adjusted with KCl), and at a myofibril concentration of 0 4–0 5 mg ml⁻¹ The reaction was terminated with 1 5 ml TCA and the liberated phosphate was determined[8] Determinations of myofibrillar ATPase activity were made at temperatures between 0 and 18 °C in the same assay conditions Appropriate controls and reagent blanks were included in all experiments

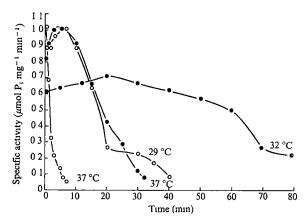
lower in the case of the Antarctic fish, 7 4 kcalorie mol⁻¹ compared with 17 3 kcalorie mol⁻¹ *Notothenia* myofibrils lost 95 % of their activity after 7 min incubation at 37 °C, whereas those of *Amphiprion* still retained 45 % of their original activity after 20 min incubation The denaturation reaction (Fig 2) followed first order reaction kinetics only in the case of the Antarctic fish In the tropical fish there was an initial activation of the ATPase activity lasting approximately 12 min, the activation in this species occurred between 37–32 °C A similar activation effect of much shorter duration was noticed in *Notothenia* at somewhat lower temperatures (32–27 °C)


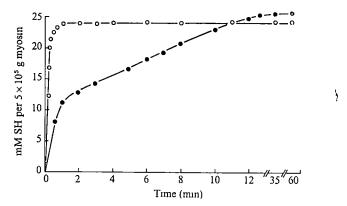


Fig 2 The thermal inactivation of myofibrillar ATPase of *Notothenia* (O) at 37 °C and 32 °C and of *Amphiprion* (●) at 37 °C and 29 °C

Myosins were prepared from the white muscle of the two species by a rapid method[9] The time-dependent exposure of SH groups of myosin (Fig 3) was determined by measuring the increasing optical density ($\lambda = 412$ nm) of the thiophenol anion with 5,5'-dithio *bis*-2-nitrobenzoic acid (DTNB) following reaction in 0 4 M KCl, 0 1 M phosphate buffer *p*H 8 0 (refs 10 and 11) The SH groups of *Notothenia* myosin became available for interaction with DTNB very much faster than those of *Amphiprion*, the reaction time being less than 1 min for the Antarctic fish compared with approximately 15 min for the tropical species

Thus, differences in activation energy (E_a), positively correlated with adaptation temperature, may play an important role in the evolutionary temperature adaptation of the enzyme Similar differences in E_a are important factors in evolutionary rate compensation in other enzyme systems[12,13] It has also been suggested that the higher catalytic efficiencies between homologous enzyme systems from cold adapted poikilotherms compared with homoeotherms may be explained in terms of an increase in weak bond formation of the activated enzyme-substrate complex in poikilotherms[14] On this basis the num-

Fig 3 The time-dependent exposure of myosin SH groups from *Notothenia* (O) and *Amphiprion* (●) measured as the increasing absorbance (412 nm) of the thiophenol anion of DTNB at *p*H 7 0

erous weak bonds involved in stabilising the higher orders of structure of cold adapted poikilotherms necessarily make the molecule more susceptible to thermal inactivation at higher temperatures This inactivation is probably associated with the disruption of certain hydrogen bonds and hydrophobic interactions between intraprotein amino acid residues, resulting in critical changes in the tertiary structure of the protein, causing loss of enzymic activity We suggest that the higher activity of the myofibrillar ATPase of Antarctic fish at low environmental temperatures is associated with weaker bonding, in other words, with a more open molecular structure In the case of the tropical fish a more compact and rigid structure seems to be necessary to give the molecule thermal stability at higher environmental temperatures Evolutionary temperature adaptation of myosins from different fish may well have important implications in limiting the present day geographical distribution of the different species

We thank the British Antarctic Survey for supplying the specimens of *Notothenia* and NERC for financial support We also acknowledge the technical assistance of Mr S E Waterson

Metabolic and insulin-releasing activities of D-glucose anomers

GRODSKY *et al*[1] proposed that glucose stimulates insulin secretion because the sugar is metabolised in the pancreatic β cells, this view of stimulus recognition was later termed the substrate–site hypothesis[2] The hypothesis has received support from observed correlations between rates of insulin release and various parameters of glucose metabolism in the pancreatic islets It is particularly striking that a triose, D-glyceraldehyde, has been shown to mimic the electrophysiological[3] and insulin-releasing[4-6] actions of glucose, D-glyceraldehyde is oxidised and dilutes $^{14}CO_2$ arising from D-(U-^{14}C)-glucose in the islets[4-6] Although the substrate–site hypothesis has been criticised (for example, refs 7 and 8), many of the arguments raised may be doubtful for reasons discussed elsewhere[9] An important challenge to the hypothesis is the observation that the α anomer of D-glucose is more effective than the β anomer in stimulating insulin secretion[10,11] For the anomeric specificity of the D-glucose recognition system to stand up as evidence against the substrate–site hypothesis, however, it must be shown that the transport, phosphorylation or further metabolism of glucose does not exhibit the same anomeric specificity in the β cell We report here that β-D-glucose is at least as effective as α-D-glucose in stimulating counter-transport of 3-O-methyl-D-glucose,

Table 1 Effects of D-glucose anomers on the islet content of glucose-6-phosphate

Sugar	μmol glucose-6-phosphate per kg dry weight		
	Primary data	Difference from control	β minus α
None (control)	87 7±18 2	—	—
α-D-glucose 6 mM	150 7±23 3	63 0± 8 4‡	—
β-D-glucose 6 mM	242 5±41 8	154 8±27 7†	91 8±22 3*
None (control)	81 3± 6 3	—	—
α-D-glucose 18 mM	183 5±32 9	102 3±31 7*	—
β-D-glucose 18 mM	213 5±24 6	132 3±30 7*	30 0±47 9

Mean values±s e m of four different mice are given in each of two experimental series Values denote glucose-6-phosphate concentration in islets after 3 min incubation without (control) or with D-glucose anomer at the concentrations indicated In addition to data for each group of islets, the mean±s e m of differences between parallel incubations are given Levels of significance by *t* test for paired observations *$P<0$ 05, †$P<0$ 02, ‡$P<0$ 01 Two-way classification (animal/sugar) and analysis of variance of data with 6 mM anomers yielded $P<0$ 05 for α-D-glucose against control, $P<0$ 001 for β-D-glucose against control, and $P<0$ 01 for β-D-glucose against α-D-glucose

increasing the islet content of glucose-6-phosphate, and diluting $^{3}H_2O$ that results from the metabolism of D-(5-^{3}H)-glucose

Figure 1 shows that α-D-glucose (Sigma) was more effective than β-D-glucose (Sigma) in stimulating insulin release Both anomers were capable of increasing the islet content of glucose-6-phosphate, but the effect of 6 mM β-D-glucose was significantly greater than that of equimolar α-D-glucose (Table 1) When islets were incubated with D-(5-^{3}H)-glucose, the production of $^{3}H_2O$ fell on addition of either non-radioactive anomer (Table 2) In keeping with the greater effect of β-D-glucose than of α-D-glucose on glucose-6-phosphate, the effect on $^{3}H_2O$ production was statistically significant for the β anomer but not for the α anomer Neither anomer induced any measurable counter-transport of 3-O-methyl-D-glucose at 37 °C (Table 3) This lack of effect probably resulted from an extremely rapid equilibration across the β cell plasma membrane resulting in an almost immediate obliteration of any driving anomer gradient When the activity of the transport system was reduced by lowering the temperature to 8 °C, both anomers induced a significant counter-transport of 3-O-methyl-D-glucose, but there was no demonstrable difference in effect between the two

These results indicate that the anomeric preference of the insulin-releasing D-glucose recognition system is not shared by the earliest steps of glucose metabolism It follows that the discriminatory behaviour of the recognition system probably cannot be reduced to that of the glucose-transporting carrier or the glucose-phosphorylating enzymes, although direct studies of the hexokinase kinetics remain to be performed This conclusion seems to create a serious difficulty for the substrate–site hypo-

Table 2 Effects of D-glucose anomers on $^{3}H_2O$ production from D-(5-^{3}H)-glucose

Group	mmol per kg dry weight		
	Primary data	Difference from control	β minus α
Control	9 26±0 88	—	—
α-D-glucose	7 68±0 76	−1 58±1 17	—
β-D-glucose	6 62±0 95	−2 64±0 66*	−1 06±1 08

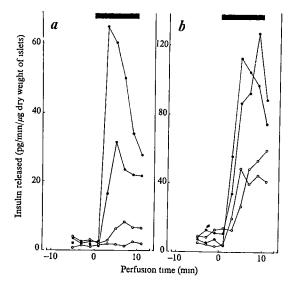
Mean values±s e m of five different mice are given Islets incubated for 10 min with 17 mM D-(5-^{3}H)-glucose in albumin-free medium produced $^{3}H_2O$ corresponding to 6 09±0 90 mmol glucose (with same specific radioactivity as in medium) per kg dry weight of islets Table shows production of $^{3}H_2O$ during same incubation followed by 5 min incubation with 17 mM D-(5-^{3}H)-glucose alone (control) or in combination with 6 mM non-radioactive D-glucose anomer As results are expressed in terms of glucose with a fixed radioactivity per mol, decreases from control values indicate dilution of the metabolically active glucose pool In addition to data recorded for each group of islets, the means±s e m for differences between parallel incubations are given
*Level of significance by *t* test for paired observations $P<0$ 02


Fig. 1 Insulin release in response to D-glucose anomers Islets were perifused with glucose-free medium without (a) or with (b) 2 mM theophylline During periods indicated by bars, the medium also contained α-D-glucose or β-D-glucose In each experiment the two anomers were tested in consecutive periods separated by 30 min of perifusion with glucose-free medium In (a) α-D-glucose was tested before β-D-glucose, in (b) the order was reversed To facilitate comparisons, the periods of perifusion with glucose have been superimposed on the time scales Each point represents the average rate of insulin release in response to α-D-glucose (●) or β-D-glucose (○) over a period of 2 min The total concentration of glucose (α plus β) measured in the effluent was 9.0 ± 0.1 mM $(8.6-9.2)$ in studies of the α anomer, and 8.8 ± 0.1 mM $(8.3-9.2)$ in studies of the β anomer Two separate experiments are shown in each diagram

Fresh islets were microdissected free-hand from adult non-inbred Umeå-*ob/ob*-mice, these islets contain more than 90% β cells In most incubations the basal medium was a Krebs-Ringer bicarbonate buffer kept at 37 °C, equilibrated with ambient air, and supplemented with 20 mM N-hydroxyethylpiperazine-N¹-2-ethane sulphonic acid (HEPES) to stabilise the pH at 7.4 In

transport experiments, Krebs-Ringer bicarbonate buffer equilibrated with O_2-CO_2 (95 5) was used Unless otherwise stated, the media contained 1 mg of bovine serum albumin ml^{-1} Polarimetric observations of D-glucose anomerisation rates at 37 °C agreed with results of Niki et al[10]

To study insulin release, the perifusion apparatus described previously[12] was modified to enable solutions of glucose anomers to be injected into a stream of basal medium passing groups of 4 islets at a rate of 35 μl min^{-1} The glucose solutions were prepared and kept at 0–2 °C for 5 min before injection, the volumes injected were small enough for the temperature to equilibrate with that of the apparatus (37 °C) before glucose reached the islets about 30 s after injection Insulin was assayed radioimmunologically, and the dry weight of islets was determined as described previously[12]

To measure glucose-6-phosphate, batches of four islets were incubated for 30 min in 25 μl of basal medium only Crystals of pure anomers were quickly dissolved in basal medium and warmed for 15 s before being added to the islets, 3 min later the islets were removed and frozen After freeze-drying (−40 °C, 0.1 Pa) overnight and weighing, islets were extracted and glucose-6-phosphate was determined[13]

Production of ^3H_2O from D-(5-^3H)-glucose was measured as an index of the combined glycolytic and pentose phosphate shunt fluxes[14] Batches of three to four islets were incubated for 30–40 min in basal medium and subsequently for 10 min in 15 μl of medium containing 17 mM equilibrated D-(5-^3H)-glucose (2.0 Ci mol^{-1}) An aliquot (5 μl) of medium containing the labelled glucose alone (control) or with non-radioactive α- or β-D-glucose anomer was then added After 5 min, metabolism was stopped with 5 μl 0.27 M HCl The ^3H_2O produced was allowed to equilibrate overnight with 500 μl water that was in an enclosing outer glass vial ^3H_2O was determined by liquid-scintillation counting, and the islets were dried and weighed as above

Affinity for the D-glucose transport system was determined as the capacity of D-glucose anomers to induce counter-transport of 3-O-methyl-D-glucose at 37 °C or 8 °C After incubation in glucose-free medium for 30–40 min, batches of three islets were equilibrated with 1 mM 3-O-methyl-D-(1-^3H)-glucose (15 Ci mol^{-1}) and 0.75 mM L-(1-^{14}C)-glucose (10 Ci mol^{-1}) during incubation in 200 μl medium for 10 min After adding 2 μl of buffer, with or without the non-radioactive glucose anomer, incubation was continued for 1 or 5 min Islets were removed, freeze-dried overnight and weighed Their content of ^{14}C and ^3H was determined by liquid-scintillation counting and intracellular 3-O-methyl-D-glucose estimated by correcting for ^3H in the L-glucose (extracellular[15-17]) space

thesis, but we do not think that it is sufficient reason for abandoning that hypothesis altogether A case for caution can be made in the light of some recent experiments on anoxic islets In such islets the concentration of fructose-1,6-diphosphate does not change with glucose in the concentration range of 1–20 mM Yet, the glycolytic flux seems to depend markedly on glucose concentration in that range (B Hellman, L-Å Idahl, J Sehlin, and I-B Taljedal, unpublished) Although the rate of islet glycolysis is often assumed to be mainly controlled by glucose phosphorylation, those observations suggest the possibility of a more complex metabolic recognition system for glucose

Another reason for caution is that rejection of the substrate-site hypothesis would require a change in our explanation of glyceraldehyde-induced and dihydroxyacetone-induced insulin release The action of D-glyceraldehyde differs from that of D-glucose in not being inhibited by mannoheptulose or glucosamine[4,5] As these inhibitors probably act on the islet hexokinases, a metabolic step that is likely to be circumvented by

D-glyceraldehyde, the difference between glucose and glyceraldehyde is readily explained by the substrate-site hypothesis If one abandons this hypothesis, however, one must postulate some direct sugar receptors that will accept a few, but not many, hexoses and that will also accept trioses Those receptors must be assumed to bind mannoheptulose in such a way that the receptor's response to glucose is blocked, while that to glyceraldehyde is not Whether or not one postulates one complicated receptor common to glucose and trioses, or different receptors for glucose and mannoheptulose on the one hand and for trioses on the other, the ensuing hypothetical construct is so complicated as to be unattractive in the absence of solid evidence of a positive kind So far, results that have been interpreted as possibly reflecting properties of direct glucose receptors in the β cells may be suggestive but are far from conclusive[18,19] Only further experiments can tell whether the answer lies in a substrate-site hypothesis developed to conform with the present data, a regulatory-site hypothesis based on direct receptors, or a combination of such mechanisms[2,4]

BCG immunotherapy of rat tumours in athymic nude mice

CONSIDERABLE emphasis is now being placed on the use of bacterial adjuvants such as bacillus Calmette Guerin (BCG) and *Corynebacterium parvum* for the immunotherapy of malignant disease While general immunostimulation by these adjuvants produces a therapeutic response against some but not all experimental animal tumours[1,2], there is evidence to suggest that a more effective suppression of tumour growth can be achieved by contacting the adjuvant with the tumour[3,4] Tumour cells injected into compatible hosts in admixture with BCG often do not produce progressively growing tumours[4] and in some cases regression of established tumour grafts can be produced by intralesional injections of BCG (ref 3) or *C parvum*[5] Clinically this is akin to the observation that cutaneous melanoma nodules may regress following intralesional injection of BCG (refs 6 and 7) Adjuvant contact immunotherapy has also been used in experimental animal studies to suppress growth of tumours developing in pulmonary or pleural sites, which are models for the treatment of metastatic disease[8-10]

Host responses are involved in 'adjuvant-contact'-mediated suppression of tumour growth since the adjuvants are not directly cytotoxic for tumour cells The relative roles of specific immunity directed against tumour-associated rejection antigens and possibly less specific reactions such as those mediated by activated macrophages is not fully understood This is emphasised by studies showing that growth of several transplanted rat tumours, including a carcinogen-induced mammary carcinoma AAF57 (ref 11), could be suppressed by contact with BCG, although these tumours were inactive or only weakly immunogenic as defined by their capacity to induce immunity against

transplanted tumour cells[12] Moreover, BCG-contact suppression of transplanted rat osteosarcomas has been observed in hosts immunosuppressed by adult thymectomy and whole-body irradiation[13]

This study was carried out to investigate further the role of host immunity in BCG-mediated suppression of tumour growth by characterising the responses to transplanted rat tumours in athymic mice Several rat tumours were studied including a carcinogen-induced fibrosarcoma (Mc7) and a hepatoma (D23) both of which exhibit significant immunogenicity, as well as carcinogen-induced and spontaneously arising mammary carcinomas (Sp15, Sp22 and AAF57), which are weakly or non-immunogenic[12] The nude-athymic mice (*nu/nu*), originally described as thymus deficient (MRC Animals Centre, Carshalton), were injected subcutaneously with tumour cells either in Medium 199 or in medium containing BCG (Glaxo freeze-dried percutaneous vaccine, 500 μg moist weight organisms) The tumour cells for these tests were derived from tissue culture lines maintained in Eagle's MEM supplemented with 10% calf serum to ensure that host lymphoid cells were not transferred It has been shown, for example, that comparable to findings with rat fibrosarcomas[14], tumour cell suspensions prepared from sarcoma Mc7 and hepatoma D23 by trypsin digestion of tumour tissue contain 9–25% glass-adherent macrophages

Table 2 Growth of second challenge of sarcoma Mc7 cells in mice rejecting a mixed inoculum of Mc7 cells and BCG

First challenge			Second challenge			
Day	No of cells in admixture with BCG	Tumour takes	Day	No of cells	Tumour takes in Test	Control
0	1×10^6	0/4	0	1×10^6	2/2	—
			18	1×10^6	2/2	3/3
0	1×10^6	0/1	0	1×10^6	1/1	—

Progressive growths were produced in athymic mice with all five tumours studied using challenge inocula of between 5×10^4 and 10^6 cultured tumour cells (Table 1) When similar tumour cell challenges were administered in the presence of BCG, however, this generally resulted in complete inhibition of tumour growth With sarcoma Mc7, for example, challenges of 1×10^6 tumour cells elicited tumours in seven out of eight mice in three separate experiments, whereas only one mouse receiving Mc7 cells together with BCG developed a tumour BCG treatment also prevented growth of 2×10^5 mammary carcinoma Sp15 and 8×10^4 mammary carcinoma Sp22 cells, although larger tumour cell challenges were not suppressed None of the tests, however, clearly established suppression of tumour AAF57 by contacting with BCG

Previous studies[4,15] in immunocompetent rats with sarcoma Mc7 showed that rejection of tumour cell/BCG mixed inocula produced a specific immune response and this induced rejection of tumour developing at a contralateral site In this case, rejection was mediated by a specific response against tumour-associated antigens since challenge with another tumour expressing different neoantigens was not rejected Comparable tests in the athymic mouse model indicate that suppression of sarcoma Mc7 by contact with BCG does not produce inhibition of a challenge with the same tumour either injected simultaneously at a contralateral site or given subsequently after rejection of the tumour cell/BCG inoculum (Table 2)

The implication from these studies is that suppression of tumour growth is not effected by a T lymphocyte mediated response, although the characteristics of the effector mechanisms are still to be elucidated These may involve a humoral antibody although previous attempts to suppress growth of sarcoma Mc7 with tumour-immune serum in immunocompetent rats have mostly been unsuccessful There is stronger evidence, however, to suggest that the effects induced by adjuvants such as BCG may be mediated by macrophages as tumour suppression is abrogated in silica-treated rats (R W B , and D G Hopper, unpublished[8]) Of more practical significance is the observation

Table 1 BCG-mediated suppression of rat tumours in athymic mice

Tumour	No of cells injected in admixture with BCG*	Tumour takes in Test	Control
Sarcoma	1×10^6	0/2†	2/2
Mc7	1×10^6	0/2	2/2
	1×10^6	1/4	4/4
Hepatoma	1×10^5	1/3	3/3
D23	1×10^5	0/3	3/3
Mammary carcinoma Sp15	2×10^5	0/3	3/3
	1×10^6	3/3	2/2
Mammary carcinoma Sp22	8×10^4	0/2	2/2
Mammary carcinoma	1×10^4	0/3	0/3
	5×10^4	1/3	2/3
AAF57	1×10^5	2/2	2/2

*Glaxo percutaneous vaccine (500 μg moist weight BCG organisms)
†None out of two, and so on

that suppression of tumour growth following contact with adjuvants such as BCG can be achieved in hosts in which immunocompetence is impaired This may have considerable bearing on the development of clinical studies where immuno-therapeutic approaches are often attempted in patients where immunosuppression is already evident as a consequence of surgery, radiotherapy and/or chemotherapy

This study was supported by a grant from the Cancer Research Campaign and the BCG vaccine was kindly provided by Glaxo Research Ltd, Greenford

Ir-gene control of immunogenicity of insulin and A-chain loop as a carrier determinant

Ir is generally believed that the B cells produce antibody against certain antigens after the helper cells recognise a determinant on the carrier part of the antigen The immune response in mice against several antigens is controlled by Ir-genes which map in the major histocompatibility (H-2) locus of the IXth mouse linkage group Details of the function of the Ir-genes are still unknown, but it is generally accepted that they control the recognition of carrier determinants[1,2]

Although several different antigens are known whose recognition is Ir-gene dependent, the specificity of this recognition mechanism as well as the structure of the carrier determinants remains unclear

To evaluate the specificity of Ir-gene dependent recognition it is necessary to have a carrier molecule with the following properties (1) It should be available in highly purified form (2) Its tertiary structure must be known (3) It should bear only one carrier determinant (4) A homologous molecule with small differences at a definite site must be available, in which these alterations do not change the remaining structure of the molecule (5) Only one of the two homologous molecules must be immunogenic in the strain under investigation

A comparison of the structure of the two molecules would

yield information about structural requirements for a carrie determinant and about the specificity of the Ir-depender carrier recognition

The insulin molecule satisfies all these requirements It is small molecule (molecular weight=5,750) so that the number c carrier determinants should be limited for steric reason: Since the mice tested have their own insulin a further restrictio of determinants may be expected Insulins of different specie show small differences in sequence, though the overall structur of the molecule is not altered The immune response against these carriers is Ir-dependent (unpublished results)

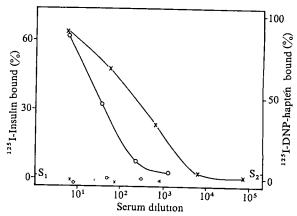
In these experiments the dinitrophenyl(DNP)-derivative c insulin with one DNP-group at lysine in position 29 of th B chain has been used This derivative was chosen because i can be isolated in a highly purified form by electrofocusing[3] hence it can be regarded as free from other contaminating substances which might be highly immunogenic[4,5] Another advantage is that the DNP-group as a haptenic determinan


Fig 1 Response of C57BL mice against DNP-lysine[B29] insulins ×, Anti-insulin response, O, anti-DNP response Pooled sera were tested Mice were injected with DNP-lysine[B29] bovine insulin (solid line) or DNP-lysine[B29] pig insulin (dotted line) Anti-DNP antibody was measured by the Farr-test using ^{125}I-α,N-(4-hydroxyphenacetyl)-ε-N-2,4-dinitrophenyl-L-lysine as hapten[11] Anti-insulin antibody was assayed with ^{125}I-bovine insulin by precipitation with 10% polyethyleneglycol[12] The antibody binding capacity (ABC) of a high titre guinea pig antiserum was set as 100% S_1, S_2, standard deviations of background Mice were injected with 20 µg antigen on day 1, boosted on day 21 with the same dose in saline and bled on day 30

serves as an internal control for the processing of the antigen by the antibody-producing B cells The response pattern is not affected by the introduction of the DNP-group, it also applies to non-substituted insulin, highly purified by electrofocusing, see Table 1

If pig insulin is used as a carrier the mouse strain BALB/c (H-2[d]) gives a high titre of anti-insulin and anti-DNP-antibody, whereas the strains C57BL (H-2[b]) and C57BR (H-2[k]) show no immune response at all (Fig 1 and Table 1) If bovine insulin

Table 1 Response of different mouse strains against pig and bovine insulins*

Strain	H-2	Immunogen	Anti-insulin antibody		Anti-DNP antibody	
BALB/c	d	DNP-Lys[B29] pig insulin	3 61	(1 22)	3 89	(1 19)
C57BL	b	DNP-Lys[B29] pig insulin	<0 1		<0 1	
C57BR	k	DNP-Lys[B29] pig insulin	<0 1		<0 1	
BALB/c	d	DNP-Lys[B29] bovine insulin	4 51	(1 24)	3 18	(1 22)
C57BL	b	DNP-Lys[B29] bovine insulin	3 08	(1 20)	2 7	(1 26)
C57BR	k	DNP-Lys[B29] bovine insulin	<0 1		<0 1	
B10 BR	k	DNP-Lys[B29] bovine insulin	<0 1		<0 1	
C57BL	b	Pig insulin	<0 1		—	
C57BL	b	Bovine insulin	3 45	(1 31)	—	

*Logarithmic mean of individual titres, s d coefficient given in parentheses Each group 7-10 mice Experimental details same as in Fig 1

is used as carrier, C57BL (H-2^b) is a responder, whereas C57BR (H-2y) is a non-responder with both insulins. The non-response of B10.BR (H-2^k) is good evidence for the Ir-control of the immune response, since this strain is congenic with C57BL, the only difference being at the H-2 locus.

BALB/c mice (H-2^d) respond to both insulins, so they obviously recognise different determinants, which are not recognised by C57BL mice. The non-response of C57BL against DNP-Lys^{B29} pig insulin may be caused by a deficiency of B cells which can respond to the pig insulin determinants but this is improbable as it has been found that (1) C57BL cannot use pig insulin as carrier for an anti-DNP response and (2) C57BL antibodies against bovine insulin do cross react with pig insulin. The only difference between the two insulins (Fig. 2) is in two amino acids at positions A$_8$ and A$_{10}$ in the A chain. These amino acids are located in a small loop which is formed by six amino acids (A$_6$ to A$_{11}$) and a disulphide bridge. The sequence of this loop is the same in pig and mouse insulin, whereas bovine insulin contains alanine instead of the more hydrophilic threonine at A$_8$, and valine instead of isoleucine at A$_{10}$. The simplest explanation is that the A-chain loop of bovine insulin is the carrier determinant which is recognised by H-2^b mice.

Pig-Insulin
Mouse-Insulin

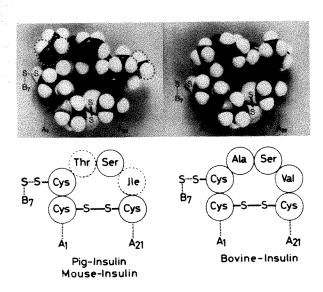
Bovine-Insulin


Fig. 2 Structure of the A-chain loop of pig and mouse insulin (left side) which does not act as carrier determinant and the homologous structure (right side) of bovine insulin which acts as carrier determinant in C57BL mice. In the upper picture the marked areas in the 'non-determinant' structure show the –CH(OH)– and the –CH$_3$ group which are lacking in the determinant.

It may be argued that the exchange of these two amino acids leads to a change in the tertiary structure of the whole molecule, so that the true determinant may not be the A-chain loop itself but another site on the molecule. But this seems to me to be highly unlikely, as this loop is a very rigid structure on the surface of the molecule, further strengthened by a second disulphide bridge at A$_7$, which links the A chain to the B chain. Therefore, it seems unlikely that changes in this loop affect the overall structure of the molecule[6]. Furthermore there is no difference in biological activity between both insulins.

Our experiments do not show whether the size of the carrier determinant is exactly that of the A-chain loop. Some adjacent parts of the molecule may be necessary or only a part of the loop may act as carrier determinant. It is also possible that, in addition to the loop structure, other sites on the molecule have to be recognised as carrier determinants. In that case, however, their contribution alone would not be sufficient for induction which we have shown in C57BL (H-2^b) mice to be dependent on the presence of the bovine A-chain loop.

It is obvious that the differences between the 'non-determinant' structure (A-chain loop of pig insulin) and the determinant (A-chain loop of bovine insulin) are rather small. There is no charge difference in the two cases and the size and steric arrangement of both structures are very similar. It seems clear that the recognition unit which can discriminate between these two structures must have a high degree of specificity.

It is of special interest to ask whether the specificity controlled by the Ir-genes is reflected in the antibody population, as has been reported[7]. If the sera shown in Table 1 are absorbed with pig insulin coupled with Sepharose, no anti-insulin activity is left in any of them (our unpublished results). Thus, it seems that the high degree of discrimination at the carrier level is not reflected at the level of antibody production, and conversely that the specificity of the antibody is not reflected at the carrier level in C57BL mice. A somewhat similar situation has been described for the hormone glucagon[8].

Finally, the finding of carrier determinants on insulin and Ir-dependence of their recognition adds same interesting aspects to the problem of insulin therapy in diabetics. Some recent papers claim that pig insulin is non-immunogenic in rabbits if highly purified[4,5]; others show the opposite[9]. It seems very likely that these discrepancies result from the different genetic background of the experimental animals.

As the insulins of man, mouse and pig have the same sequence in the A-chain loop it seems very likely that the bovine insulin loop can also act as a carrier determinant in man. This assumption is confirmed by the high incidence of anti-insulin antibody in patients treated with the commonly used bovine insulin compared with those treated with pig insulin. It seems reasonable to assume that in man, too, an Ir-gene controls the recognition of this determinant. Until now there has been only weak evidence that such an Ir-gene is located in the HL-A locus of man which corresponds to the H-2 locus in the mouse[10]. Experiments designed to establish a correlation of the ability to make antibody against bovine insulin with a certain configuration in the HL-A locus would provide evidence for this assumption.

I thank Dr E. Rüde for a sample of the DNP-hapten and B. Bergmann for technical help. This work was supported by the Deutsche Forschungsgemeinschaft.

Function of peptide antibiotics in producer organisms

PEPTIDE antibiotics in the producer organisms have been ascribed a wide variety of roles, ranging from evolutionary relics and waste products to elevated control in metabolism (see refs 1 and 2). No hypothesis, however, has yet found

general acceptance. A frequent suggestion is that these antibiotics may have an important regulatory function during the sporulation process of the producer cells[3,4]. We have recently reported, however, the existence of a bacitracin-negative mutant of *Bacillus licheniformis* which sporulates normally[5], thus ruling out a direct role for the peptide antibiotic in the formation of spores in this species. To find out whether this mutant is a true non-producer of bacitracin or not, we have compared the bacitracin synthetase complex in this mutant with that of the bacitracin-producing mother strain *B. licheniformis* AL. This suggests that the mutant is not able to produce any bacitracin as a result of a defective enzyme complex.

The non-ribosomal synthesis of the peptide antibiotic bacitracin[6-8] is in principle similar to the protein thiotemplate mechanism[9] for the synthesis of gramicidin S and tyrocidine. The purified enzyme complex from the bacitracin producer *B. licheniformis* AL was resolved in three complementary fractions (A, B, and C) using affinity chromatography. The chromatogram (Fig. 1a) was nearly identical to that obtained using bacitracin synthetase from *B. licheniformis*, ATCC10716 (ref. 10). Each of the three enzyme components activated a different group of the amino acids (measured by the $^{32}PP_i$–ATP exchange reaction) which make up the bacitracin molecules. All three components were necessary for the bacitracin synthesis. Any exchange of corresponding enzyme components

Table 1 *In vitro* synthesis of bacitracin by combined bacitracin synthetase components

Enzyme component	Radioactive incorporation in bacitracin spot (c.p.m.)
A	85
B	120
C	138
AC_0	115
B_0	83
A+C	94
A+C+B_0	1010
B+C	190
AC_0+B+C	155
A+B+C	795
AC_0+B_0	90

Bacitracin synthetase from *B. licheniformis* AL and SB319 was fractionated by affinity chromatography as described in Fig. 1. A slower increasing gradient gave the following cross contamination of the fractions A, B, C, AC_0 and B_0 after precipitation with solid $(NH_4)_2SO_4$ (to 80% saturation) and carrier BSA: Component A contained 8% C; B—4% C; C—15% A; AC_0—3% B_0; and B_0—3% AC_0. The enzyme components were combined (20 µl of each fraction), and the bacitracin synthesising activity was measured (after 15 min incubation at 37°C) using ^{14}C-L-isoleucine (85,000 c.p.m., specific activity 100 Ci M^{-1}) as described[10]. As a result of the experimental separation techniques[8] a certain background count was observed.

from strain AL and strain ATCC10716 did not reduce the amount of bacitracin produced (data not shown).

The chromatogram obtained by fractionating the bacitracin synthetase of the bacitracin-negative mutant *B. licheniformis* SB 319 was different. Using the same affinity chromatography column, the enzyme complex was resolved into two fractions (AC_0, and B_0). Fraction AC_0 activated the same amino acids as the enzyme components A and C of the mother strain, and fraction B_0 activated the same amino acids as enzyme component B (Fig. 1b). There was a marked difference, however, in the degree of the $^{32}PP_i$–ATP exchange reaction with enzymes from the producer and the non-producer. When the non-producer was collected later in growth, the enzyme component AC_0 seemed to be arbitrarily split up. The activation of L-glutamic acid was performed by a component dissociated from AC_0.

The combination of enzyme fractions from the producer

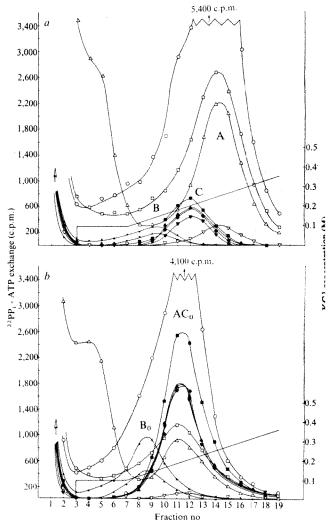
and the non-producer showed that enzyme component B of the non-producer was able to participate in the bacitracin synthesis of the producer strain instead of enzyme componer B, but enzyme component AC_0, when combined with intact enzyme component B from the producer, was not able to do s (Table 1). Similar results were obtained when enzyme components A, B, and C from ATCC10716 were used. This sugges that the bacitracin synthetase of the bacitracin-negativ SB319 was defective. This defect seems to influence th activation sites for the amino acids and the affinity between th


Fig. 1 Fractionation of bacitracin synthetase by affinity chromatography. *B. licheniformis* AL (*a*) and SB319 (*b*) were grown in the medium of Haavik and Thomassen[5]. The cells were collected at an absorbance of 4.5 measured in a Spectronic 20 spectrophotometer at E_{650}, lysed with lysozyme, and the enzyme was partially purified by streptomycin sulphate precipitation and ammonium sulphate precipitation (to 55% saturation) as described by Fröyshov and Laland[8]. The 55% $(NH_4)_2SO_4$ fraction obtained from 250 ml culture was applied to an affinity chromatography column (3.0 × 1.6 cm) prepared from 2 g Sepharose 4-B (Pharmacia Fine), and 3, 3′-diamino-dipropylamine, with L-leucine as ligand as described[8]. The column was eluted with 0.05 M potassium phosphate buffer (*p*H 7.5) containing 0.2 M $MgCl_2$ and 0.1 mM dithiothreiol (60 ml h^{-1}). A KCl gradient (0.1–0.4 M) was added to the buffer, and $^{32}PP_i$–ATP exchange activity dependent on the L-amino acids isoleucine (○), cysteine (□), leucine (△), glutamic acid (▽), lycine (+), ornithine (×), phenylalanine (▼), histidine (■), aspartic acid (▲), and asparagine (♦) was measured in 0.2 ml aliquots of each fraction (6.5 ml) as described[10]. Total amount of radioactivity in each incubation mixture was 120,000 c.p.m. The radioactivity (40–50 c.p.m.) in control tubes (without any amino aicds) was subtracted. The signs A, B, C, AC_0, and B_0 indicate the enzyme fractions used in further experimentation.

enzyme components corresponding to A and C of the producer

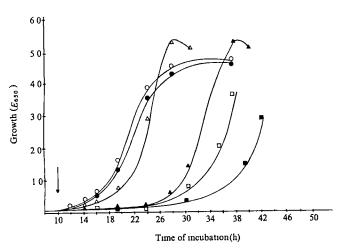
Previously[5], neither external nor internal bacitracin were detected yet the mutant SB319 sporulated normally, indicating that bacitracin has no regulatory role during sporulation With reports of other antibiotic-negative mutants able to sporulate[11,12], evidence seems to be accumulating against a possible connection between peptide antibiotics and sporulation of producer organisms


Fig 2 Growth of *B lichemformis* strains at different cultural conditions Growth of strain SB319 in the medium with 0 0001 g $MnSO_4l^{-1}$ (O), with 0 1 g $MnSO_4$ l^{-1} (△), with 0 1 g $MnSO_4$ l^{-1} and 50 IU bacitracin ml^{-1} added (□) Arrow indicates time of addition The corresponding growth curves of strain AL are marked ●, ▲, ■, respectively Growth was measured as E_{650} using a Specronic 20 spectrophotometer Growth occurred in 500 ml Erlenmeyer flasks incubated at 37 °C at about 360 r p m on a New Brunswick rotatory shaker (Model G–53) The defined medium used had the following composition (g l^{-1}) L-glutamic acid (15 0), L-leucine (2 0), L-histidine (0 2), L-alanine (0 2), citric acid (1 0), KH_2PO_4 (0 1), K_2HPO_4 (0 1), $MgSO_4$ $7H_2O$ (0 2), $FeSO_4$ (0 01), $MnSO_4$ H_2O (varied between 0 0001 (low) and 0 1 (high) as noted in the text), pH 7 0 The inoculum consisted of spores[13]

The production of peptide antibiotics after growth is assumed to be a fundamental property of the microbial cell, and thus the search for their function has been focused on the stationary phase metabolism[2-4] We have reported, however, that the lag in antibiotic production in relation to growth may be pH-dependent[13,14] Peptide antibiotics may therefore normally be synthesised, and may also function throughout active growth The observations that tyrocidine and linear gramicidin production under certain conditions are paralleling growth[15], that polymyxin E production occurs in the log phase of growth[16], and that penicillin[17], tyrothricin[18], and gramicidin S (ref 19) can be produced in continuous culture, support this view

Both the producer and the non-producer strains of *B lichemformis* show similar sporulation and also identical reactions in standard biochemical tests[5] To determine the function of bacitracin during growth, the two strains were grown at several different cultural conditions At present only a few significant differences between the producer and the non-producer have been discovered The bacitracin-negative mutant showed a markedly increased resistance to high concentrations of Mn^{2+} In media with low manganese both strains showed almost identical growth (Fig 2)

Active manganese transport in *B subtilis* has recently been described Too high concentrations of manganese in the medium inhibited growth as a result of an efficient uptake of the ion[20,21] Our bacitracin-negative mutant, SB319, was only slightly inhibited at manganese concentrations which strongly inhibited the producer strain AL, indicating that the manganese uptake of the mutant was markedly less efficient than that of the producer If bacitracin participates in the transport of

Mn^{2+}, this difference between the two strains could be explained Furthermore, the addition of bacitracin to the bacitracin-negative strain should eliminate this difference Indeed, when bacitracin was added to the non-producer, growth was markedly inhibited in media with high manganese (Fig 2) Adding bacitracin to the same culture grown in low manganese showed no effect The addition of bacitracin to the producer strain increased the inhibitory effect of high manganese concentration (Fig 2)

The possibility that peptide antibiotics normally act as carriers of ions through membranes in the producer organisms has been suggested[22,23] This agrees with the strong metal binding properties of peptide antibiotics[24,25], and their ability to modify membrane permeability[26] Since the bacitracin-negative mutant, SB319, is able to grow without producing any bacitracin, this mutant must take up manganese by some other means Our results indicate, however, that bacitracin is able to influence this manganese transport by increasing the efficiency of the uptake of the ion By depriving the non-producer and the producer strains of manganese by adding EDTA to the medium, the bacitracin-negative mutant was markedly inhibited whereas the bacitracin producer grew well By adding bacitracin or excess manganese to the EDTA-inhibited mutant, growth was promoted (H I H, unpublished) This indicates that bacitracin production may be necessary in environments with a very low manganese content

The antimicrobial effect of bacitracin may be an interaction with the cytoplasmic membrane of susceptible organisms[26] This effect is dependent on the presence of certain divalent cations such as Mn^{2+} (ref 27), the function of which may be to promote the cell–antibiotic interaction[26] A similar mechanism may operate in the producer strain bacitracin may increase the uptake of manganese by promoting the interaction between manganese and the cytoplasmic membrane

In conclusion, we have shown that the bacitracin-negative mutant (SB319) has only a partially functional bacitracin synthetase complex This mutant is probably not able to produce any molecules of bacitracin A comparison of the producer and non-producer of bacitracin in different cultural conditions indicates that the peptide antibiotic bacitracin participates in the transport of manganese through the bacterial membrane Further experimentation will be necessary to determine whether this is causal or coincidental

Improvement of antisera against polypeptide hormones

THE sensitivity of immunoassays is probably decreased by endogenous antigenic material blocking some of the antibody binding sites[1]. To remove antibodies generated against polypeptide hormones from endogenous antigenic material derived from the immunised animals, we took advantage of the capacity of sodium iodide to break the antigen–antibody bond

Antisera against lys_8–vasopressin (Ferring, Malmo) and val_5–angiotensin II (Ciba, Basel) were generated in rabbits with repeated intramuscular injections of immunogen coupled to albumin[2] Angiotensin was labelled with [125]I (IMS 3, Amersham) as described previously[2] In the case of arg_8–vasopressin (Ferring, Malmo) the metabisulphite step was omitted Only monoiodinated material was used, as confirmed by isoelectric focusing Specific activity for angiotensin II was 450 μCi μg^{-1}, and for arg_8–vasopressin 650 μCi μg^{-1}

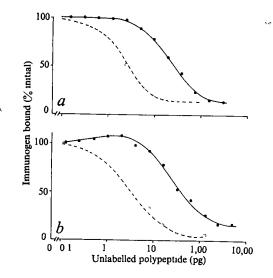
Antisera were diluted at ratios of 1 700–1 2,000 with 0 9% NaCl and treated with 2M NaI (final concentration) at room temperature for 2 h, then dialysed for 48 h at +4 °C against


Fig. 1 Increase in sensitivity *a*, Dose–response curve for val_5–angiotensin II (mean of five experiments) before (●) and after (○) treatment of the antiserum with NaI *b*, Dose response of arg_8–vasopressin (mean of eight experiments) shows a paradoxical increase in binding[5,6] before (●) and a shift to the left with disappearance of the paradoxical binding after (○) iodide treatment

0 9% NaCl The diluent for binding studies with vasopressin was 0 15 M phosphate buffer (*p*H 7 5), containing human serum albumin (Kabi, Stockholm) 1 mg ml^{-1}, Na_2–EDTA 10 mM, L–cysteine 20 mM neomycin sulphate (Upjohn) 0.1 mM, and for angiotensin the same buffer with OH–quinoline 1.5 mM (Merck) instead of L–cysteine

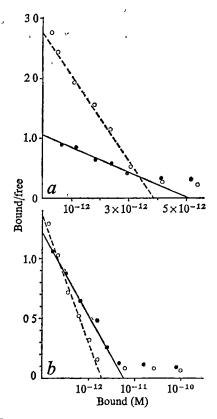
The procedure of sodium iodide treatment and subsequent


Fig 2 Increase in affinity Scatchard plots[4] for antisera to angiotensin II (*a*) and lys_8–vasopressin (*b*) before (●) and after (○) NaI treatment (mean of three experiments) The apparent affinity constants[3] were 2 1 × 10^{-13} M^{-1} and 7 1 × 10^{-13} M^{-1}, respectively, for untreated and treated antiserum to lys_8–vasopressin, and 1 7 × 10^{-13} M^{-1} and 5 9 × 10^{-13} M^{-1} respectively, for angiotensin II

dialysis increased the sensitivity of the dose–response curves for arg_8–vasopressin and angiotensin II by factors of 12 1 and 10, respectively (Fig 1) This increase in sensitivity could not be explained as a dilution effect because conditions were designed to give maximal sensitivity[3] both before and after NaI treatment of the antiserum Scatchard plots[4] (Fig 2) indicated modification of the apparent affinity constants of the antisera with iodide treatment, and some loss of total binding capacity We conclude that this resulted from the unmasking of high affinity antibody binding sites blocked by endogenous antigenic material

The dose–response curves for unlabelled analogues of angiotensin II and vasopressin, taken as a measure of specificity, were shifted (Fig 3) This resulted in an increased specificity for val_5–angiotensin II compared with the 2–8 heptapeptide and 3–8 hexapeptide fragments In the vasopressin assay system, iodide treatment of the antiserum caused the highest increase in sensitivity for unlabelled lys_8–vasopressin compared with arg_8–vasopressin and pressinoic acid In other words, the assay became more sensitive to the hapten (lys_8–vasopressin) actually used to immunise rabbits against vasopressin We believe that the changes in apparent specificity observed resulted from the unmasking of binding sites with a high affinity for this molecule

The paradoxical binding of vasopressin (that is, increase in bound label with low doses of unlabelled polypeptide), which has been used by others in highly sensitive radioimmunoassays for ACTH–(ref 5) and LH–releasing hormone[6], disappeared with sodium iodide treatment (Fig 1) Thus, paradoxical binding may be caused by endogenous antigen interfering with the binding of iodinated polypeptide On the other hand, iodide treatment may induce changes in the steric configuration of antibody molecules resulting in a loss of paradoxical binding

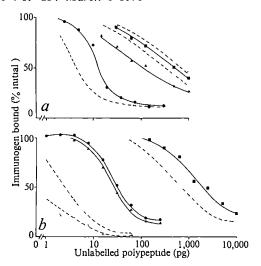
Our data suggest that any procedure for removal of endogen-


Fig 3 Modification of specificity a, Dose response curve of val_5-angiotensin II (●) radioimmunoassay is shifted to the left (○), curves of 2–8 $ileu_5$-heptapeptide (▲) and 3–8 $ileu_5$-hexapeptide (■) are shifted to the right (△, □) after sodium treatment, resulting in a decreased cross reaction with heptapeptide and hexapeptide Mean of two experiments b, Curves of lys_8-vasopressin (●), arg_8-vasopressin (▲) and pressinoic acid (Ferring, Malmo, ■) were shifted to the left after iodide treatment (○, △, □) The result was increased sensitivity for lys_8-vasopressin compared with arg_8-vasopressin and a decreased cross reaction with pressinoic acid after iodide treatment Mean of three experiments

ons antigenic material which causes minimal damage to the antibodies should be considered when adequate sensitivity of immunoassays cannot be achieved with known designs of competitive protein binding assay[3] The treatment of antisera with chaotropic substances such as sodium iodide may also result in a modification of antiserum specificity

Conservation of primary structure in 16S ribosomal RNA

THERE is no doubt that the large ribosomal RNAs play specific roles in ribosome function[1] Yet the thrust of experimentation during the past 5 years indicates clearly that the biologist tends to view these roles as structural, function being reserved by and large for the ribosomal protein components[2,3] Whether or not this prejudice can be maintained remains to be seen In any case, the existence of an approximate sequence for a 16S rRNA provides a basis for detailed characterisations of this molecule[3,4] Here we begin to define 16S rRNA function by localising the major conserved regions in the molecule through a comparative analysis of 27 prokaryotic 16S rRNA primary structures

Comparative sequencing has been used effectively to

investigate the structure and function of a number of small macromolecules Although this approach is not feasible for the larger ribosomal RNAs, partial sequencing techniques can be used effectively One can, for example, characterise a large RNA by comparative cataloguing[5,6], that is, completely delineate the products of T_1 ribonuclease digests of RNA species from various organisms In practice, this can be done using present techniques[7] with only a few oligonucleotides eluding sequencing

When comparing two such oligomer catalogues, a prime consideration is the size for which oligomer sequence coincidence implies true primary structural homology Statistical considerations[5] indicate that coincidence among oligonucleotides of length six or more (pentanucleotides are marginal) provides strong evidence for primary structural homology in a sequence of 1,600 nucleotides When three or more catalogues are considered, the continuous appearance of any oligonucleotide of length five or more increases the probability of true homology, as the prospect of multiple chance coincidence shrinks rapidly as the number of catalogues considered increases

During the past few years, complete ribonuclease T_1 catalogues have been developed in our laboratory for the 16S rRNAs of a wide range of prokaryotes, including Enterbacteriaceae[8–10], Spirillaceae[10], Cyanophyta[11] and Athiorhodaceae[12], and there are unpublished results from this laboratory for Bacillaceae, Brucellaceae, Achromobacteraceae, Pseudomonadaceae and Lactobacillaceae It is now appropriate to consider the extent to which each of the characteristic oligomers (pentanucleotides and larger) of *Escherichia coli* 16S rRNA is conserved across phylogenetic lines These 114 oligonucleotides are shown in Table 1 together with the number of organisms in which each has been found They are arranged in their reported order of occurrence[4] in the 16S rRNA sequence and numbered alternately so that nomenclature adjustments for minor sequence revisions can be accommodated readily

When the relative occurrence data of Table 1 are depicted graphically (Fig 1), the pattern of conservation characterising 16S rRNA primary structure is displayed vividly The oligomers that appear in more than half the organisms screened are considered to be conserved, while those found in at least 24 of the 27 organisms are termed universal Figure 1 suggests nine possible concentrations of conserved and universal oligomers (1) oligomers 217–223, (2) 185–207, (3) 167–177, (4) 153–159, (5) 127–137, (6) 107–113, (7) 75–83, (8) 41–51 and (9) 31–35 Although the conserved oligomers are divided evenly between the two halves of the sequence, the universals are not (19 out of 27 are in the 3' half) Thus, as might be expected, six of the nine highly conserved regions are in the 3' half of the molecule Indeed, the 3' half of the molecule seems to alternate quite regularly between regions of extremely high and low conservation

The most prominent region of conservation, No 2, is very close to the 3' end of the molecule, between oligomers 185 and 207 The 12 large oligomers in this region together encompass approximately 100 nucleotides The final oligomer in this grouping, $U\overset{*}{C}ACACCAUG$, is present in only 14 organisms The clearly related sequences, $UCA\overset{*}{C}ACCAUG$ and $UCA\overset{*}{C}ACCACG$ (asterisks indicate post-transcriptionally modified nucleotides), however, account for 12 of the remaining organisms

Several additional regions deserve further comment Region No 1, the 3' terminal region, is excised intact by colicin E3 (refs 13 and 14) In a large group of prokaryotes, this region contains the kasugamycin-sensitive sequence[15] which may provide a clue to the region's functional significance Region No 6 comprises merely three oligomers but may be somewhat larger as it lies immediately adjacent to a gap in the sequence Three oligomers not currently placed that might appear in this gap are the highly conserved CAAACAG and the possibly universal copies of two pentamers, AUUAG and AAAUG (Table 1 and footnotes a and k)

In addition to locating the conserved regions, it is important

The first column lists the 114 ribonuclease T_1 oligonucleotides ($\geqslant$ pentamers) in the order in which they have been placed by Ehresmann *et al* in th 16S rRNA sequence unless indicated otherwise in the footnotes[4] The oligomer sequences used, however, are those determined by Uchida *et al* rather than those reported by Fellner *et al* [17], unless otherwise indicated in the footnotes The second column indicates the number of organisms in whic the given oligomer has been found The final column indicates by (A) those oligomers which have been found to be excised by ribonuclease T_1 fron intact 30S subunits (T U and C R W, unpublished), by (B) those oligomers which have been found to be substituted by kethoxal at the 5' guanosin and by (C) those substituted at the 3' guanosine[16]

Notes to Table 1

(a) This oligomer is found in two copies in E coli and most 16S rRNAs from other Enterobacteriaceae and Spirillaceae, but in one copy in many other organisms Since Ehresmann places only one copy, it is not clear that position 33 is the correct location for the universal copy If this universal oligomer is ultimately placed elsewhere, conserved region No 9 will no longer exist

(b) Ehresmann locates two copies of ACCAG (No 41 and No 173), one copy of ACACG (No 47) and no copies of CACAG Previously Fellner reported one of each Uchida found 1–2 copies of ACACG, only one copy of ACCAG and no CACAG Thus these three oligomers are currently ambiguous and are treated as such on Fig 1

(c) This oligomer has been reported as present in 2–3 copies by Uchida and 3 copies by Fellner Yet only two have been located by Ehresmann (No 45 and No 91) and one of these (No 91) is considered to be fractional

(d) Due to the inability of Fellner and Ehresmann to distinguish between CACCG and CCACG, these two oligomers (No 69 and No 195) are not uniquely placed at this time and are thus represented by open bars on Fig 1

(e) The sequence previously listed by Uchida was that obtained by Fellner This oligomer has now been independently examined and the sequence is found to be as reported here (L Z and C R W, unpublished)

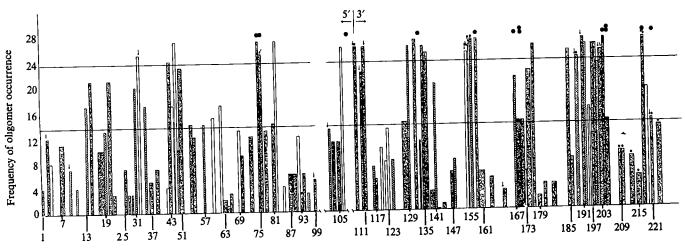
(f) This oligomer has been re-examined with more powerful techniques and the sequence given here is taken to be correct rather than that previously reported by Uchida

(g) These two isomers are placed here in a fashion consistent with the results of Santer and Santer[2a] However, Ehresmann suggests the opposite placement

(h) No evidence for this oligomer has been found in our preparations of E coli 16S rRNA (see Uchida) Although it is found in eight other organisms, it is not found in any Enterobactericeae or Spirillaceae 16S rRNA so far examined The oligomer is thus indicated on Fig 1 by an open bar

(i) This sequence and what seems to be the earlier version of it CAUCACG, reported by Fellner has not been found in E coli by Uchida nor has either been found in any other organism Its position is indicate(on Fig 1 as a fractional solid bar

(j) Two copies of this oligomer are reported to be very close to each othe in this area of the sequence The sequencing is, however, rather incomplet(here, and Ehresmann indicates the first copy is questionable Althougf Uchida reports 1½ copies, no other Enterobacteriaceae or Spirillaceae i: known to have two copies Thus only one copy (No 151 is omitted) i: included in Fig 1 Furthermore, the order of No 155 and No 157 is that suggested by Noller[16] rather than that of Ehresmann

(k) Fellner reports only one copy of this oligomer and Ehresmanr locates only one Uchida, however, reports 2 and every member of th(Enterobacteriaceae and Spirillaceae so far examined has been found definitely to contain 2 Thus this oligomer has been represented as ar open bar on Fig 1


(l) This oligomer represents a minor correction to the sequences given b) Uchida (C R W, unpublished)

(m) This oligomer was previously unsequenced by both Uchida and Fellner and is now known to have the sequence indicated (C R W, unpublished)

(n) The sequence previously listed by Uchida for this oligomer was that reported by Fellner This oligomer has now been independently examinec and the sequence is found to be as reported here (C R W, unpublished)

(o) Although the 3' terminal oligonucleotide has not yet been fully sequenced in this laboratory, it is known to vary across phylogenetic lines Certainly the first five and probably the first seven nucleotides, AUCACCU are found in all but one case, and the remaining bases in all cases are a mixture of uracils and cytosines (C R W *et al*, unpub- lished)

(p) These two oligomers have not yet been located in the E coli 16S rRNA sequence by Ehresmann They are, however, reported by both Uchida and Fellner

85

Relative oligomer position in 16S rRNA primary structure

Fig 1   Distribution of phylogenetic conservation in 16S rRNA Each bar represents one of the characteristic oligonucleotides of the *E coli* 16S rRNA sequence The ordinate shows the number of organisms which have been found to contain that oligomer and the abscissa indicates their exact position in the sequence of Ehresmann *et al* [4], numbers are those given in Table 1 The width of the bars is proportional to the size of the oligomers The known gaps in the sequence are indicated by (——/ /——) on the abscissa The solid bars designate unique oligomers containing six or more bases or a post-transcriptionally modified base The cross hatched bars represent unique oligomers of length five The open bars represent the most consistent placement of those oligomers which are not unique, their placement must be considered highly tentative Arrows above the bars indicate the points of kethoxal substitution, positioned so as to indicate whether the substituted guanosine is at the 5' or 3' end of the oligomer[16]. The small dots indicate known points where T_1 ribonuclease can remove an oligonucleotide from the intact 30S subunit The large dots indicate the location of post-transcriptionally modified bases that are found in *E coli* or other 16S rRNAs

to consider which of them are exposed on the 30S ribosomal subunit This problem can be approached in a number of ways (1) by determining points of nuclease attack on the 30S subunit, (2) by locating post-transcriptionally modified nucleotides (since an RNA segment must be exposed at some time during ribosome assembly to allow attack by the modifying enzyme), and (3) by determining points of attack with chemical modifying reagents All these techniques have been used, and the results are included in Fig 1

The location of post-transcriptional modifications as defined by *E coli* oligomers and those found in related sequences of the other 26 organisms correlate completely with the conserved segments Each of the six conserved regions in the 3' half of the molecule and the adjacent one in the 5' half of the molecule contains modifications in some if not all organisms No modification is found in an unconserved region of the molecule Kethoxal modifications of the intact ribosome have been made and identified[16] These correspond strongly with the highly conserved regions Nos 2, 4 and 6 which contain respectively 2, 4, 3 and 3 kethoxal attack points Attack points found by T_1 ribonuclease digestion of intact 30S subunits (T U and C R W, unpublished) also follow this general pattern This last study indicates that oligomers 209–223 are especially susceptible to attack Santer and Santer[17] found oligomers 207–217 to be susceptible in a similar study

The ribosomal protein-binding sites so far characterised seem by and large not to coincide with the conserved regions[18-21] All the primary binding proteins (with perhaps one exception) can be localised in the 5' half of the molecule There does exist, however, a ribonucleoprotein subparticle containing proteins S7, S9, S13 and (usually) S14 (ref 22), that includes some oligonucleotides from region No 2 (its 5' portion) This in itself is not proof that region No 2 actually contains a protein-binding site

If this apparent negative correlation proves entirely correct it raises an interesting problem Since a functional 30S ribosome chimaera can be constructed from *E coli* 30S proteins and *B stearothermophilus* 16S rRNA[23], one would assume homology of the protein-binding sites in the two organisms The apparent contradiction would be resolved if homology were in this instance to be primarily in secondary or tertiary structure and so on There is a precedent for such an interpretation in the 5S rRNA This molecule is functionally interchangeable between the

above two organisms[24], yet it is likely that its ribosomal protein-binding sites are again not in the regions of highest primary structural conservation[25,26]

The results reported here show the extent to which each of the characteristic ribonuclease T_1 oligomers of *E coli* 16S rRNA is conserved The universal and highly conserved oligomers cluster, falling into not more than nine regions These groupings are not uniformly distributed throughout the molecule, but rather are concentrated in the 3' half where they alternate regularly with regions of low conservation At least seven of the regions are located on the surface of the 30S particle (at some stage), including all of those in the 3' half of the molecule These results strongly suggest that important functional features of the 16S rRNA are located in the 3' half of the molecule Since little or no correlation exists between these conserved regions and known ribosomal protein binding sites, the implication is strong that large areas of the RNA are directly involved in ribosomal function

absorption spectrum was obtained with a maximum at 260 n1 the ratio of A_{260} to A_{235} was 2 28 The temperature-abso bancy curve for MgDNA, dissolved in deionised water, shown in Fig 1, T_m for MgDNA was 85–87 °C, the return c cooling was about 50%, and the hyperchromicity was 43° This contrasts with the T_m for spleen NaDNA in deionise water, which was 71 °C In both cases, the initial absorban at 260 nm was closer to 0 95 The melting profile for MgDN was steeper than that for NaDNA, indicating extensive stabi sation of the DNA double helix by Mg(II) The ratio of Mg(I to DNA(P) was 0 518, indicating one magnesium per tw nucleotide phosphates MgDNA was also stable to hydrolys by pancreatic DNase I in the absence of added Mg(II) additic of Mg(II) to the above solution resulted in rapid degradatic of the DNA[5] DNase I requires free Mg(II) for activity, thi very little of the Mg(II) in MgDNA was available

Solutions of single-stranded NaDNA were prepared t heating to 95 °C and cooling quickly, solutions of nativ bovine NaDNA in deionised water This process was repeate until the melting curve of the resulting solution showed n rise in absorbancy when heated

Formation of triple-stranded bovine DNA *in vitro*

EVIDENCE for a triple-stranded complex of polynucleotides was reported for homopolymer RNAs by Felsenfeld *et al*[1] in 1957 They detected a drop in absorbancy at 260 nm for a mixture consisting of two parts polyadenylic acid (poly(rA)) and one part polyuridylic acid (poly(rU)), during a continuous variation mixing study of the two homopolymers Addition of 0 1 M $MgCl_2$ produced the greatest triple-strand formation with a minimum absorbance at 67 mol % poly(rU), 33 mol % poly(rA)[2] Since this early work, many triple-stranded complexes have been identified, including combinations of homopolymers of deoxyribonucleotides and ribonucleotides, Riley *et al*[3] reported a triple strand formed by the homopolymers dA dT. dT They also reported the caesium sulphate buoyant densities of various double-stranded and triple-stranded homopolymers In all cases, the triple-stranded homopolymer had a greater buoyant density than the analogous double-stranded homopolymer We now report evidence for the formation of triple-stranded bovine DNA *in vitro*

We used a magnesium salt of bovine DNA, which was prepared from bovine spleen by substituting $MgCl_2$ for the sodium chloride–sodium citrate medium (SSC) in a standard DNA preparation procedure[4] Sodium xylene sulphonate (Naxonate G) was added to precipitate protein The MgDNA so prepared was purified by reprecipitating with cold 2-propanol three times, and the final precipitate was dried by washing first with ethanol and then with acetone When the purified MgDNA was dissolved in 5×10^{-4} M $MgCl_2$, the usual DNA

Fig. 1 Temperature-absorbancy curves for MgDNA in deionised water Absorbance was measured at 260 nm ○, Heating curve, ●, cooling curve

Fig 2 Continuous variation mixing curves for mixtures of native bovine MgDNA and denatured NaDNA The unbroken line is the expected curve for no interation, % denatured NaDNA is mol %, and the absorbance was measured at 260 nm *a*, MgDNA and NaDNA in 0 1 M $MgCl_2$, *b*, MgDNA and NaDNA in deionised water

Continuous variation mixing curves, as used by Riley[3] and others, were made to determine the interaction of MgDNA and denatured NaDNA Figure 2 shows mixing curves for the two DNAs (*a*) in the presence of 0 1 M $MgCl_2$ and (*b*) in water only The unbroken line is the expected curve for no interaction (0 1 M $MgCl_2$ was found to be the optimum concentration of $MgCl_2$ in our studies, and for homopolymers, by Rich[6]) Figure 2 clearly shows a one-to-one interaction between double-stranded MgDNA and single-stranded Na-DNA, in the presence of Mg(II) ion These experiments were

Table 1 Summary of data from continuous variation mixing curves for double-stranded bovine DNA with single-stranded NaDNA

Type of DNA Double strand + single strand	Added salt	mol % SS NaDNA at A_{260} minimum	DNA ratio at minimum
MgDNA + NaDNA	None	No min	—
MgDNA + NaDNA	0 1 M MgCl$_2$	50%	1 1
NaDNA + NaDNA	SSC	No min	—
NaDNA + NaDNA	0 1 M MgCl$_2$	No min	—
MgDNA + Salmon sperm NaDNA	0 1 M MgCl$_2$	No min	—

repeated with double-stranded NaDNA plus single-stranded NaDNA in the presence of SSC as well as 0 1 M MgCl$_2$ The experimental results are summarised in Table 1, no interaction was apparent in these mixtures That the reaction may be species specific is indicated in the last experiment reported in Table 1, where denatured salmon sperm NaDNA was substituted for denatured bovine DNA, and no drop in absorbance was observed

The time required for the formation of the triple-stranded complex was less than 30 s at room temperature Felsenfeld[2] found that triple-strand formation took about 24 s with the homopolymers rA and rU in 0 12 M MgCl$_2$

The amount of triple-stranded bovine DNA formed was estimated by the drop in absorbancy at 260 nm (Fig 2) as compared with the values reported for homopolymers If we assume that the homopolymers formed a 100% triple-stranded complex, then our DNA was between 15% and 20% triple-stranded We attempted to separate the various species of DNA (single-stranded NaDNA, double-stranded MgDNA, and triple-stranded) present in the one to one denatured NaDNA and native MgDNA mixture in 0 1 M MgCl$_2$, by sucrose density gradient centrifugation and by CsCl density gradient centrifugation In all such attempts, we found only one peak caused by DNA, which indicated one species of DNA in the solution The CsCl$_2$ buoyant density of this DNA was

no further increase in absorbance at 260 nm was observed The minimum time required was 4 h The digest was then separated by gel filtration through a column of Sephadex G-200, 40×1 cm, pretreated with 0 10 M MgCl$_2$, which was also used as the eluant Unhydrolysed DNA was eluted immediately after the void volume and accounted for 18% of the applied A_{260} units The balance of the 260 nm absorbing material appeared in a complex peak about ten 2 5-ml fractions later, which corresponded well to the elution volume of a mixture of known deoxyribonucleotides The fractions containing the DNA were pooled, and then concentrated by addition of dry Sephadex G-200 After swelling and water regain had occurred, the mixture was filtered with suction This final filtrate contained DNA which was resistant to DNase I digestion, that is triple-stranded DNA, and was used to determine the CsCl buoyant density of the pure triplex Triple-stranded DNA had a buoyant density of 1 726 g cm^{-3} compared with double-stranded NaDNA and MgDNA (both were 1 699 g cm^{-3}) and agrees with the values reported for triple-stranded homopolymers[3,7,8]

The temperature–absorbancy curve for the pure triple-stranded DNA fragments in 0 1 M MgCl$_2$ is shown in Fig 3 The T_m was 79 °C and the hyperchromicity was 33% The T_m and hyperchromicities of our three DNAs are compared in Table 2 Since the melting curve of the triplex produced a single break, the three strands seem to be bound equally and are quite stable in 0 1 M MgCl$_2$

Table 2 Comparison of melting temperatures (T_m) and hyperchromicities of single-stranded, double-stranded and triple-stranded DNA

DNA	T_m (°C)	Hyperchromicity (%)
Denatured NaDNA*	65	13 5
Native MgDNA†	86	43
Triple-stranded DNA*	79	33

* In 0 1 M MgCl$_2$
† In deionised water

The biological significance of triple-stranded DNA can only be speculated upon, but it is valuable as a model of possible DNA RNA triple-strand formation during transcription Zubay[9] postulated such a triple strand and concluded that its formation required a widening of the major groove of the DNA A short triple-stranded DNA segment has also been proposed as an intermediate in DNA replication[10,11] The fact that MgDNA was required for triple-strand formation may be explained by the effect of Mg(II) on the DNA helical structure, in contrast to Na$^+$, Mg(II) would be expected to bring the phosphate moieties of the opposing strands closer together, thus the major groove of the DNA helix would be widened and triple-strand formation would be possible

Fig 3 Temperature–absorbancy curve for pure triple-stranded bovine DNA in 0 1 M MgCl$_2$

1 681 g cm^{-3}, when compared with the bouyant density of native DNA (1 699 g cm^{-3}) A single species of DNA, resulting from the above mixture, can be visualised as a core of double-stranded MgDNA, to which is attached single-stranded DNA to form short segments of triple-stranded DNA, with many dangling tails of single-stranded NaDNA, and many areas of MgDNA that are solely double-stranded

To determine the true buoyant density and melting curve of pure triple-stranded DNA, it was necessary to remove all single-stranded and double-stranded segments from the crude single triplex This was done by exhaustive digestion of the triplex mixture with pancreatic DNase 1 (2 µg ml^{-1} at pH 6 8) until

The phosphorylated site of calf thymus F2b histone by the cyclic AMP-dependent protein kinase

THE phosphorylation of histones is a complex process which occurs at different stages of the cell cycle[1-3] Different types of histone kinases are responsible for the phosphorylation of the seryl (or threonyl) residues of the histone fractions One of them is the ubiquitous cyclic AMP-dependent protein kinase[4,5], whereas the histone kinase predominant in mitotic cells is not activated by the cyclic nucleotide[6] The cyclic AMP-dependent enzyme of rat liver, phosphorylates the seryl residue in the position 37 of calf thymus F1 histone, and the growth associated histone kinase catalyses the phosphorylation of other seryl and threonyl residues of the F1 fraction[4-6]

The cytosol and nucleus of human tonsillar lymphocytes also contain cyclic AMP-dependent and independent histone phosphorylating enzymes[7,8] In vivo, F2b histone is phosphorylated to a small extent only[1-3] but in vitro it is about as good a substrate as F1 for both of the lymphocyte histone kinases, and a better substrate than the other histone fractions The lymphocyte enzymes, however, differ from each other in their kinetic parameters and in the

sites of phosphorylation of the F2b fraction[7,8] When pho phorylation was carried out using the cyclic AMP-indeper dent enzyme four different, approximately equally phosphorylated peptide fragments were detected on th two dimensional paper electrophoretic pattern from th tryptic digest of F2b histone fraction, whereas one of ther was phosphorylated preferentially when the reaction wε catalysed using the cyclic AMP-dependent enzyme[7,8] Th same single peptide fragment of calf thymus F2b wε phosphorylated also by the cyclic AMP-dependent enzym of rat Harderian gland[9], hence, this specificity seems to b the common feature of cyclic AMP-dependent protei kinases of different species and of different tissues

The amino acid composition of the tryptic peptide fraξ ment phosphorylated by the cyclic AMP-dependent enzym has been determined (Table 1) The complete amino aci sequence of the F2b histone fraction is known[10], and th amino acid composition of the phosphorylated peptide i consistent with that of only one tryptic fragment of F2t There is a single tryptic peptide containing glutamic acid serine, trypsine, valine and lysine together, that is, th residues from Glu-35 to Lys-43 (Fig 1) In addition, th C-terminal sequence of the isolated peptide, (Val-Tyr-Lys COOH, see legend to Table 1) agrees well with that of th F2b fragment in question

The phosphorylated segment of F2b contains two sery

Fig. 1 Amino acid sequence of calf thymus F2B histone[10]

Table 1 Amino acid composition of the phosphorylated peptide fragment of calf thymus F2b histone

Amino acid	Concentration (nmol)	Molar ratio to lysine
Serine	280	2
Glutamic acid	160	1
Valine	280	2
Tyrosine	220	>1, 5*
Lysine	150	1

F2B was purified according to the method of Oliver et al[12] and phosphorylated using the cyclic AMP-dependent protein kinase of tonsillar lymphocytes The incubation mixture contained 10^{-6} M cyclic AMP and 1 25×10^{-4} M γ ^{32}P-ATP (16 mCi mmol^{-1}) Generally one out of every five molecules of histone was phosphorylated in these conditions The incubation procedure, the precipitation and tryptic digestion of the phosphorylated samples were performed as described previously[4,5] The ^{32}P-labelled phosphopeptide was isolated as before[4,5] applying two-dimensional paper electrophoresis at pH 6 5 and at pH 1 9 The labelled peptide fraction was further purified by ascending paper chromatography (pyridine isoamyl alcohol water—35 35 30 by volume) A sample of the purified phosphopeptide was hydrolysed in boiling HCl (5 7 N) for 24 h at 105°C, and the amino acid analysis was performed on a JEOL JAH 6 analyser The C-terminal sequence of the isolated peptide was determined according to the method of Sajgó and Dévenyi[13] A sample of the peptide (40 nmol) dissolved in 0 1% NH$_4$ HCO$_3$ was digested by carboxipeptidase A and B (SERVA, free of trypsine and chymotrypsine) at 37°C The molar ratio of enzyme to substrate was 1 100 Aliquots were taken out after 0, 5, 15, 30 and 60 min digestion into 0 01 M HCl The aliquots were freeze-dried then resolved in 0 01 M HCl and were put on a resin-coated chromatoplate (FIXION 50-X8, Chinoin, Hungary) Control mixture of all the amino acids in 0 01 M HCl was also put on the chromatoplate After ascending chromatography in sodium citrate buffer (Na$^+$ 0 4 M, citric acid 0 4 M, pH 3 28) at 45°C, the amino acid spots were developed using ninhydrin–cadmium–acetate–collidine reagent After 5 min digestion the only detectable amino acid was lysine After 15 minutes digestion a small amount of tyrosine appeared and the amount of lysine increased In the last two samples a spot in the position of valine could be observed, beside the strong tyrosine spot
*This method destroys a part of the tyrosine residues

groups in positions 36 and 38 Our data provide no information as to which one is modified but the electrophoretic pattern suggests that only one of them is phosphorylated Assuming phosphorylation of Ser-36, thus Arg-34-Lys-35 of F1 and Arg-33-Lys-34 of F2b are identical residues in the vicinity of the sites phosphorylated by the cyclic AMP-dependent kinase, although the surrounding sequences differ significantly in calf thymus F1 (ref 11) and F2b histone fractions Considering the total molecules, however, the similarity between the positions of the phosphorylated groups is obvious and the modification occurs adjacent to the N-terminal clusters of basic amino acids in both cases

reviews

ACCORDING to the foreword, the course on which this book is based aimed at providing both a comprehensive survey of basic topics and a review of some more specialised topics of great current interest and intrinsic importance On that criterion it fails For example, I find it hard to find the great current interest or intrinsic importance in a three page contribution on rocket soundings in Poland But then, I'm not Polish

Had this book been the proceedings of a conference of atmospheric specialists then its contents could not have been faulted, but on the basis of the stated aim I have a vision of eager young workers, new to aeronomy, lusting for understandable and interesting surveys What they will receive is a set of 16 uncoordinated and rather specialised lectures that present an unbalanced view of the upper atmosphere

I graded the articles for interest and clarity by pretending that I was a first year graduate student The results

α Tides (Lindzen), Electrical Structure (Webb), Rockets and Remote Sensing (Heath *et al*), Lower Ionosphere Morphology (Harnismacher), Winds and Turbulence (Muller), The F Region (Rishbeth)

β Photochemical Models (Hesstvedt), D Region Measuring Techniques (Rumi), Composition Studies (Van Zahn), Corpuscular Effects (Mariani)

γ The other six articles

The γs account for only 50 pages, but their omission would have im-

Structure and Dynamics of the Upper Atmosphere (Proceedings of the Second Course of the International School of Atmospheric Physics) (Developments in Atmospheric Science, 1) Edited by Franco Verniani Pp xiii+535 (Elsevier Scientific Amsterdam, Oxford and New York, 1974) Dfl 160, $61 50

proved the book They are low quality research contributions that should have been sent to the appropriate research journals It is a mockery to have a four page article grandiosely entitled "Mid-Latitude Sporadic E" (Bossolasco and Elena), it fails to do credit to an exceedingly important subject

Had I graded the contributions in terms of their completeness then almost all of them would have been relegated to the βs and γs We are presented with 40 pages on winds and turbulence in the meteor zone without the merest whisper of sporadic E (E_s) Harnismacher, to his credit, includes E_s morphology in his excellent contribution but it would come as a surprise to Verniani's scholars at Erice that theories actually exist to account for E_s They would have left the school, after 535 pages of heavy monologue, unaware of spread F, polar cap absorption, the plasmapause, the polar wind, incoherent scatter radars, the acoustic

cutoff frequency, aurorae and the details of the dynamo current

Overall, I think the editing was lamentable The greatest omission was of an introductory chapter that defined a few things Like upper atmosphere, ionosphere, stratosphere, D region, and so on Also, the book is a very uneven mix between theory and experiment Some topics (such as tides) are only dealt with theoretically, and only the experimental details of others (for example, lower ionosphere) are presented To complete the confusion, half of the articles use c g s units whereas the other half use m k s

On the credit side, the editor has carefully systematised everybody's bibliographies, the author index and subject index are well prepared, there are surprisingly few typographical errors, and Elsevier have done a fine job on the printing and binding I unintentionally dropped the book from the back of my speeding motor scooter, an event which the binding has uncomplainingly accepted

I would only recommend this book to those already actively engaged in work on the upper atmosphere A few of the articles are excellent, though the active worker will have seen much of the material before in one form or another Aeronomy desperately needs a lot less edited collections of unrelated papers and a few more single or co-authored works of simple exposition and of authority I hope that *Developments in Atmospheric Science, 2* provides the latter □

THIS book would make a good present for the serious aquarist and would be a useful addition to any departmental library which gives a thought to fostering an interest in freshwater fish and their care It is not a new book, but a new edition of an old one An earlier issue was reviewed by Phillip Greenwood in these pages (*Nature*, **198**, 516, 1962) and he found much good in it I concur with his view

The new edition is compact, strongly bound, and presented as two volumes The bulk of the text comprises descriptions of the species grouped by families Each description contains general information at the family level, with distribution charts, and the accounts of the species include more detailed material, biometric data, and illustrations For the aquarist's special needs information as to behaviour, food

preferences and environmental requirements with special reference to breeding, are also given

Some changes have been made in the

Fish out of date

F. R. Harden Jones

Freshwater Fishes of the World By Gunther Sterba Vol 1 pp 1–456, vol 2 pp 457–877, 191 plates (Studio Vista London, 1974) £12 50

new edition Illustrations that were coloured in previous editions are here in black and white, and a whole set of new colour photographs have been included they are good The page size has been somewhat reduced and although this makes the book more compact, there is the disadvantage that

drawings originally scaled to natural size are now 10% too small

And what of the book's deficiencies? These must be measured against one's expectations, I would set those out as 'identification', 'classification', and 'description' The book fails to clear only the first of these hurdles in that there is no key reference to families, for as Denys Tucker—translator and reviser—notes, that section was stillborn A pity, because it would have put the finishing touches to what is a useful work There are some trivial mistakes —what book is free from these?—and I would be disappointed to learn that they had been carried through from earlier editions And no changes have been made to the select bibliography, in which the most recent publication is dated 1962, for £12 50 a purchaser could expect to be taken into the 1970s

Allelopathic response

Allelopathy (Physiological Ecology A Series of Monographs, Texts and Treatises) By Elroy L Rice Pp x+ 353 (Academic London and New York, September 1974) $25 00, £12 00

MANY people are familiar with the interactions between microorganisms which involve the release of chemical toxins, yet the general public and even many biologists are probably unaware of the importance of such toxic sub-stances in interactions between higher plants But the concept is by no means new De Candolle was perhaps the first biologist to suggest such a possibility in 1832 Yet, in spite of that, this book can justifiably claim to be the first volume in English to be devoted to the subject That alone serves to illustrate the neglect which the study of allelo-pathy has suffered, it may also be re-garded as an indication of the difficulties and uncertainties which surround such a study

The definition of allelopathy used in the book is that of Molisch, which in-cludes chemical interactions between plant and plant and between micro-organism and plant The study of chemical interactions between plants and animals (included in the term 'allelochemics' as used by R H Whit-tacker) is thus excluded The emphasis of the book is ecological, and the role of allelopathy in the development of community structure and composition forms a theme linking several sections, whether dealing with phytoplankton, weeds in an old field succession, fire cycles or vegetation pattern in stable communities

Two chapters on the role of allelo-pathy in agriculture and horticulture deal briefly but effectively with the considerable volume of work which has been done on this subject A further section is devoted to the chemistry, physiology and mode of action of the inhibitors involved in allelopathy The final chapter on chemical reactions be-tween animals and plants is rather in-congruous It is too brief to do justice to a fascinating aspect of plant toxicity and since it does not fall within the definition of allelopathy used by the author, it hardly seems necessary

Overall, however, the coverage is good and the bibliography excellent In emphasis and treatment this is essen-tially a personal view of the subject by Elroy Price He is well known for his work and ideas on the inhibition of bacterial processes—such as nitrifica-tion—during the development of stable vegetation, and on the role of allelo-pathy in delaying succession in some instances by the attainment of domin-ance by species with inhibitory proper-ties These subjects and others like them are developed fully in this book

At times readability and flow ar sacrificed for the author's concern t give practical details (even to the grad of Whatman filter paper used in ex periments), but summary paragraphs a the end of chapters make up for this

I cannot agree with the author's con cern to divorce the concept of allelc pathy from that of competition Th plant which has evolved allelopathi properties is comparable with a specie of coarse or robust morphology in tha it is able to substitute space for resource in competitive interactions On acquiring such space the resourc may become freely available to th plant which would not necessarily re quire any degree of efficiency in tap ping it To say that the struggle fo space is not competition is, in m opinion, an exercise in semantics

This book is a full and stimulating account of a sadly neglected subject, a such it should be read by all practisir ecologists, physiologists, agriculturalis and foresters It is to be hoped that r production will give impetus to furthe research in an area where many prol lems, both theoretical and practical have yet to be solved **Peter D. M**

Nuclear spectroscopy

Nuclear Spectroscopy and Reactions vols 40-A and 40-B Edited by Joseph Cerny Part A, pp xvii+518, part B, pp xvii+711 (Academic New York and London, October 1974) Part A $44 50, £21 35 Part B $49 50, £23 75

THE rate of growth of the physical sciences is nowadays so great that ever the specialist has difficulty in keeping abreast of more than a very narrow field Yet he needs to know more than this, so it is very important tha specialists should periodically summaris the work in their field for the benefit of those working in related areas

Professor Cerny has succeeded admir-ably in bringing together the work of a group of well known specialists in nuclear spectroscopy and reactions, and has arranged it in four volumes

The authors of the articles in the first two volumes—covering nuclear instru-mentation and research in nuclear spectroscopy—are among the foremost authorities on their subjects and in many cases are leading the most active groups in the field The result is most impressive and contains within a rela-tively manageable compass expert and up-to-date coverage of many of the important growth areas in nuclear spectroscopy The volumes will be essential reading for all engaged on work in this field The subsequent volumes, on gamma-ray spectroscopy and theoretical analysis, will be eagerly awaited   **P. E. Hodgson**

The unloved treaty

IN two months time those countries which have ratified the Non-Proliferation Treaty (NPT) will be reviewing, under UN auspices in Geneva, the first five years of the treaty There is no doubt that in 1970 the hopes (at least of the non-nuclear countries) were that by 1975 the NPT would be a solid foundation on which to build further arms-control measures, aimed at progessively steering the world away from the contemplation of nuclear solutions to political problems Certainly in the past five years nobody has fired a nuclear weapon in anger, though the NPT could hardly claim much credit for that On the other hand the prospects for a nuclear-free future are no better than they were in 1970 and the NPT foundations have been neglected—indeed show signs of crumbling

The treaty bans the development of nuclear explosives of any kind in non-weapon states in exchange for promises that the benefits of peaceful applications will be extended to those states There are some notable absences from the list of ratifiers, a few non-ratifiers have signed but will not ratify for fairly specific reasons, but the following countries *inter alia* have not even declared interest in the treaty at all   Argentina, Brazil, Chile, China, France, India, Israel, Pakistan, Portugal, South Africa and Spain The weight of the three original nuclear powers which used to reassure other countries that treaties were worth signing is now counterbalanced by the weight of three other nuclear powers who want nothing to do with this treaty

The reasons for the failure of the NPT to catch on are all too obvious—it is asking for major concessions from the 'have-nots' in exchange for minimal concessions from the 'haves', and it is a trap for have-nots who sign and find that their unfriendly neighbours do not follow suit Much has been written on the extent to which vertical proliferation, the continued refinement of the nuclear nations' arsenal, causes offence to non-nuclear powers There has been remarkably little public discussion of the real reason for the diffidence of most potentially nuclear states towards the NPT—the fear of unbalanced horizontal proliferation which, in the absence of simultaneous accession by all states, cannot be ruled out

It is widely believed that the NPT contains assurances to non-nuclear states in the event of nuclear attacks This is not so A resolution of the UN Security Council, which appeared when the NPT was first opened for signature, replaces any binding commitment by a general welcome for the intention of the UK, the USA and the Soviet Union to act "in accordance with the Charter" were any non-nuclear-weapon state, party to the NPT, to be the victim of an act, or the object of a threat, of nuclear aggression The catch is that the Security Council with all its possibility for veto would be the vehicle for action Small wonder that countries which have refused to sign the NPT abstained on this resolution also

Finally, the NPT promised that benefits from peaceful nuclear explosives would be made available "through an international body" Negotiations were to start "as soon as possible" Back in 1968 when the treaty was drafted, the Plowshare programme in the United States was languishing In major excavation projects, for instance, costs for even chemical-explosive techniques were double those for conventional techniques Since then, however, things have changed dramatically The factor of two in cost is now a factor of much less than one, in the future the same will be true of nuclear explosives

In the Soviet Union, in an entirely different political and physical environment, the cross-over point must have been reached much earlier, for nuclear explosive projects burgeoned in 1970 and now run at the rate of 10 a year Thus the hopes of many in 1968 that peaceful applications would never be economic and thus might not obstruct arms control discussions have been proved unfounded

So where is the international body? It is now five years since the treaty came into force and the International Atomic Energy Agency (IAEA) has yet to establish any body to consider the political and legal aspects of an international service In the meantime, the Soviet Union, it is said, took it upon herself to offer India nuclear explosives for peaceful purposes but was rebuffed Some minds had better be made up soon on the establishment of a body, the next bilateral deal may be accepted

The IAEA has not been entirely inactive Technical panels have exchanged a substantial amount of information and non-nuclear countries have been party to all this But the political nettle has yet to be grasped

The reasons are a combination of bureaucracy, politics and genuine concern for safety There is a resistance in Vienna to the accumulation of yet more duties for a secretariat already fully extended There is concern that the IAEA might include only NPT-ratifiers amongst beneficiaries of nuclear technology And there is a fear that the apparent legitimisation of nuclear explosive transfers will lead to the even wider dissemination of potential weapons material, and will be an encouragement to even more countries to think nuclear This last is a fairly weak objection now that events have overtaken hopes that peaceful explosions might not prove viable The IAEA itself these days puts out fairly enthusiastic publicity for nuclear explosives in its technical reports There is, however, some substance to fears that the service might be tied to the NPT Any restrictions of this sort, although at first sight a means of bolstering up the treaty, would in the long run diminish IAEA initiatives by driving non-ratifiers into more implacable opposition

On many grounds the NPT has not lived up to expectations and could even be seen as creating opposing nuclear camps Will anyone have the courage in May to suggest the treaty be scrapped and new approaches tried?

AS a country Britain is living beyond its means, and it is surely no more than good sense to consider ways in which we can meet more of our needs from our own resources, among which agricultural resources figure prominently In the past 100 years or so the latter have been evaluated against a background of abundant world supplies of food, available freely except for short periods of war and post-war restriction, and to be purchased cheaply in relation to the price of the industrial goods we had to offer in exchange We have rarely had an explicitly formulated agricultural policy, but the *de facto* policy that has grown up has resulted from the impact of these world forces

The world situation has changed, dramatically and to our disadvantage Although agricultural production has increased enormously over the past quarter century, the increase has been taken up by population growth and by the increasing sophistication of the diets of affluent countries Thus, now that the basic resources on which farm production depends—land, fertilisers and energy—have become scarce and costly, we have no margin to protect us against shortage, prices have risen greatly in rich countries, and poor countries face widespread hunger In this context we should reappraise our agricultural assets, with a view to meeting from them more of our needs

In Britain we enjoy a generous, not to say extravagant, diet, including a high proportion of animal products The livestock industry has come to depend very heavily on concentrate feeding, and home feed production is augmented by massive imports of coarse grains and protein feedstuffs In present circumstances this is a profligate way of feeding ourselves, and we know that we could devise a palatable and nutritionally adequate diet at much less expense in real resources, and with much less dependence on imports A reduction in the heavy consumption of animal products would make a major contribution to Britain's balance of payments, and would help ease the world food situation

The corresponding changes in the production pattern of British agriculture would require extensive planning, and would take some years to implement in full It is, therefore, particularly important that we should start planning without delay Planning of this order is beyond the time scale of political parties and exceeds the sectional interests of farming organisations But it is vital if agriculture is to contribute more substantially to the solution of our economic problems Some of the major topics to be considered in such an enterprise are out-

Agriculture and nutrition

Almost overnight the scientific community at large has discov of much more attention. Sir Joseph Hutchinson argues for a : (left). Professor Jean Tremolières points to the need to stimula

lined here, in the hope of encouraging interested people to get together, to study agricultural policy in depth, and to make known their conclusions

● **Cropping pattern.** Cereals are the basic foodstuffs of the human race In the British diet we consume approximately 90 kg a head a year directly, and use about 360 kg a head to feed to livestock which produce meat, milk and eggs For this we grow 13–15 million tonnes and import 8–9 million tonnes How would one implement a decision to (a) halve, or (b) eliminate cereal imports? This would fall under two heads, first, the replacement of imported cereals used in human food, chiefly by growing good milling instead of low quality winter wheats, and replacing some of the spring barley crop with good quality spring wheats, and, second, the reduction of cereal-based livestock production to match the reduction in the availability of feed grain Of this we have the experience of the Second World War, when pig and poultry stocks were drastically cut back, and beef production was limited to the available grass feeding acreage

Other crops would not be so directly affected Potatoes would probably remain about as at present There might be considerable debate about sugar beet, but considering the need of the Third World for access to industrial markets, and the disfavour with which sugar is regarded by nutritionists, it seems likely that the crop should be stabilised at a level appropriate to use as a rotation crop in arable farming

In a diet with a lower meat content, vegetables might have a larger place, and vegetable crops might be increased Oilseeds are almost entirely imported, and oilseed crops should be reviewed Ley breaks in arable rotations would assume greater importance, and are considered in relation to the maintenance of fertility

● **Fertility levels** The present high fertility of British farm land has been achieved by the liberal, and at times almost profligate, use of fertilisers Now that these have become expensive and scarce, there is no doubt that considerable savings can be made by more discriminating fertiliser practice Greater savings are to be gained by better distribution of animal manure,

and by the use of leguminous crops : augment the nitrogen supply The: two are interrelated, since the tenden(to separate crop production froi animal industry has resulted in an u convenient concentration of anim; manure on livestock farms and an abai donment of grass/legume leys on arab. farms

The redistribution of crops and stoc in order to maximise the conservatic of fertility would be the most importai and the most difficult consequence (this kind of reappraisal of British agr culture The rundown of intensive liv stock enterprises would involve writii off capital in intensive housing, ai the reintroduction of grazing livesto: on intensive arable farms would requr investment in fencing, water supl and some winter housing How much At what rate? And where?

● **Human nutrition.** Human nutri'io lags behind animal nutrition on accour of the difficulties of experimentatio with human subjects The diversity c opinion among eminent nutritionists : to the causes of the 'diseases of affli ence' is sufficient indication of th uncertainties of the subject Neverth less, the existence of diseases associate with affluence is not in dispute, an this, together with economic need an the limitations of world food suppl; is a powerful reason for devising die that are less demanding on resource: and perhaps less menacing to health

In conclusion, these are three majc areas in which we have substanti; room to manoeuvre If we are t exploit the freedom of choice open t us with a view to realising the fulle: potential of our agricultural resource some of us must get down to the har work of studying these topics, an charting a course of action in detai Some groups are already concerned 1 this area, notably the Joint Consul ative Organisation recently set up b the Ministry of Agriculture, Fisherie and Food to give guidance on researc priorities, but we need a wider asses: ment of the place of British agricultur in British economic policy Are w interested to provide a factual basis o which informed opinion can be buil or are we content to stumble from Pric Review to Common Agricultural Polic negotiation without real understandin of where we are going? ⊏

ashionable subjects are worthy
n of British agricultural policy
al research (right).

THROUGHOUT the crises of our time—the financial crisis, the troubles of society, the energy crisis—our idol, science, has remained unquestioned. Now the time has come to ask ourselves what science can contribute.

This is what has just been done in the field of human nutrition by a British committeee convened jointly by the Medical and Agricultural Research Councils (MRC and ARC) under the chairmanship of Professor Neuberger. Its report is the collective testimony of a number of scientists with long and converging experience. Until now nutrition has appeared to be limited to certain specialised functions, to the study of deficiency diseases and to dogmatic ideas on diet. In fact, nutrition is not just a particular function of living beings; together with immunology and genetics, it is one of three universal concepts which relate human beings to their environment and to the society in which they live. There was a need to restore nutrition to its true dimension as a synthesis of sciences, a culture which stimulates and fertilises, and to get away from an approach which had become too purely analytical.

Why should it be surprising that it is the bread man eats which serves as the starting point for taking a new look at our attitude to science?

The disorganised state of our knowledge of nutritional science could not last. Nutritional requirements as laid down by the expert committees are a mass of contradictions, arising from a scarcity of facts which in any case have little meaning. For example, energy requirements represent the actual consumption of the reference man; yet this Apollo is a man of our industrial society whom we know to be too fat and who eats too much. On the other hand, protein requirement has a physiological basis, the minimum values having been derived from measurements made in the laboratory during brief experimental balance periods. No society actually lives at this level, however, since if energy requirements are met, even the simplest diet would provide surplus protein according to these standards. The values recommended for vitamins are saturation values which have no clear physiological meaning. Hypovitaminosis is rarely seen now, but nevertheless people are trying to use these recommended values

as a basis for labelling and advertising of dietetic products in the USA and in France. Supplementation with amino acids or iron has mostly been based on economic considerations.

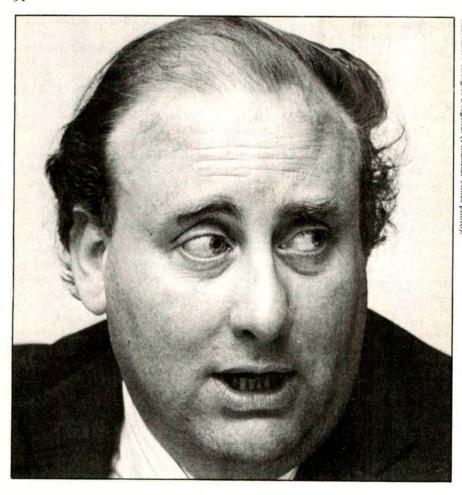
In the field of diseases associated with nutrition, the inability of classical physiology to explain obesity is obvious. Measurements made over 10 minutes are extrapolated to 24 hours. The physiologist applies the law of surface area which is only valid to $\pm 30\%$; yet a systematic error of 10% would represent a weight change of 13 kg a year. The cause of degenerative disease of the heart and blood vessels has been attributed variously to the percentage of calories from fat, the ratio of EFA to NEFA, to sugar and to cholesterol. Yet this is a global state, a multifactorial syndrome, in which the causal factors are interdependent.

It is the ideas expressed in the Neuberger Report, the lines of thought, the strategy, which are important, not the details. The sergeant-major will always find something wrong with the buttons: there are no references, and some important points about dietary behaviour have been neglected, but the positive side of the report is such a relief and offers such hope that one can overlook the omissions. Doctors, biochemists, physiologists, agronomists, toxicologists, dietitians, the food industry and sociologists have all co-operated and succeeded in producing a unification of knowledge which is a truly significant synthesis.

This group of academics has emphasised the 'social' function of research in relation to the health of the individual and of the community and has tried to apply this research to a number of social and medical problems. To those of us who have lived for the last 10 years with the research policy of the Institut Nationale de la Santé et de la Recherche Médicale and of the Conseil National de Recherches Scientifiques, this report under the signature of Professor Neuberger is a bomb which will breach the ramparts.

The evidence given here shows nutrition as a special area of interaction between man and his environment. The problems of toxicity and pollution are looked at from the biochemical and physiopathological point of view and the metabolism of foreign substances has been dealt with in the same way as that of nutrients.

It is, however, at the molecular and cellular level of organisation that the most practical problems of medicine, of toxicology, of *l'alimentation* have to be solved. Again it must be realised that it is the synthesis, the common language, the ideas, which will allow specialists in each sector of this huge spectrum to understand one another clearly in order to produce the illu-

mination of which man and his society are in need.


Some of the principal nutritional problems have been mentioned as illustrations. It is not possible to summarise what is already a summary of 180 pages. This kind of committee does not usually adopt an attitude so widely based on biology, so critical and so positive. There are certainly many points for discussion, but there are so many positive suggestions that all nutritionists will be obliged to meditate on them. One is more stimulated by this report than by a classical scientific publication. It seems to me very possible and desirable that different national committees should take this document, study it in depth, fill the gaps and propose different approaches to certain points.

It is appropriate here to mention that the French effort, small though it is, operating through the Fondation Française de Nutrition and the Committee on Human Nutrition of the Centre National de Coordination des Etudes et Recherches sur la Nutrition et l'Alimentation, has embarked without previous consultation on a programme which, in proportion to its resources, is completely in the same spirit.

The topics selected are identical: nutrient requirements, an appraisal of the states of overnutrition (cardiovascular disease, obesity) and of undernutrition, a study of nutritional factors in infancy in relation to prevention of disease, toxicological aspects of food safety, and the dietary behaviour of individuals and communities. The spirits are ready and willing to work together; the means remain poor. The report from the UK is going to catalyse the timid French efforts.

To go even further, it would be desirable for Britain and France jointly to hold meetings and symposia on nutrition (once or twice a year to start with) at which points of view and communications of original work could be presented. The Nutrition Societies, the public bodies such as the MRC and ARC in the UK and the CNCERNA in France and the Nutrition Foundations could provide the impetus for such an arangement. The first step would be the formation of a working group, aware of the present deficiences of the subject and of the necessity to keep in touch all the time with the practical implications of food production and the maintenance of health and with fundamental research and the proper role of administrative and financial structures. The ultimate object would be to inspire research, and thus to develop a knowledge to use as a means in the service of the well being of the individual and the community. □

Marshall the energy

A profile of Eric Varley's Chief Scientist by David Fishlock

THE late Sir John Cockcroft, founder-director of the Atomic Energy Research Establishment, Harwell, in the early 1950s, was offered the post of Chief Scientific Adviser to the Cabinet. He accepted but retained his job as director of one of Britain's biggest research centres. Few today even recall that Cockcroft ever held the post in White-hall, so slight was his influence in the broader affairs of government. Dr Walter Marshall, present Director of Harwell, was expressly warned of this unhappy pecedent when, last summer, Mr Eric Varley, Secretary of State for Energy, offered him the post of Chief Scientist to his science-starved department. Marshall, however, would none-theless accept only on condition that he retained his job as Director of Harwell, Britain's—if not Europe's—most powerful energy research and development centre.

For Marshall, still a theoretical physicist at heart, whose own research earned him election into the Royal Society while still in his thirties, the most worthwhile job in the world is to be chief executive of this big science machine. Knowing that this is so is one important reason why morale is so high among the 5,000 staff of the Research Group of the UK Atomic Energy Authority (UKAEA), for which Marshall is the Board member responsible. But the Whitehall post, in which he would take a seat alongside the four existing deputy secretaries under Sir Jack Rampton in the Department of Energy, could expand vastly his influence over energy research and development in Britain. Coordination in this area, at a time when the emphasis was shifting from competition to conservation, would plainly be an important part of the role of government, as it became increasingly deeply embroiled in the activities of private as well as state-owned energy industries.

Even so, the twin jobs of advising both the Energy Secretary and his own boss Sir John Hill, Chairman of the AEA, could begin to work only if there existed a special relationship between Hill, as the Energy Secretary's adviser on the largest single sector of energy research and development, and Marshall, as his personal research adviser. But Marshall holds Hill in high esteem, not least for the support given Harwell during the difficult years when the laboratory was attempting to re-

build its reputation with a new an far more commercial approach, in fac of great scepticism from th scientific community as well as fror private industry. They devised the kin of formula that can work only betwee two people in closest rapport, to avoi mutual interference within each other parish in advising the Secretary c State for Energy.

Walter Charles Marshall, 43, joine Harwell from Birmingham Universit in 1954. Just six years later he becam Head of Theoretical Physics, and i 1966 Deputy Director, Two years late he was appointed Director of Harwe under Dr J. B. Adams, then Boar member for research of the UKAEA When Adams resigned the followin year to take charge of CERN's plan for the 300 GeV accelerator, Marshal was appointed Director of the Researcl Group of the UKAEA. In 1972 h became its Board member for research with full control of its research budge of £25 million.

By this time the prodigious energie of the burly young Welshman were al ready a legend—and not only at Har well. In 1969 Dr Alvin Weinberg, ther Director of Oak Ridge Nationa Laboratory, reflecting upon a perioc Marshall had spent with him in hi early thirties, remarked to me that had he remained much longer he would have taken over Oak Ridge.

But Harwell, by the mid-1960s, was presenting a challenge of a different kind. It was a research centre searching for a new mission. The basic physics and chemistry required to make nuclear weapons and lay the foundations for a nuclear power programme had been taken up by other laboratories, more firmly orientated towards engineering requirements. Harwell, some said, was becoming increasingly irrelevant. (*Nature* itself, in an editorial in October, 1967, argued that it should be closed down.)

One course of action open to the UKAEA was to cut the Research Group—then some 6,000 strong—back to a size commensurate with the mission remaining, mostly work for the fast reactor. This implied a reduction to about one-third of its size. The Government itself was well aware at the time of one drawback to this course of action, that those industries most urgently in need of new technical talent, such as the mechanical engineering industries, were the least likely to be enthusiastic about hiring redundant Harwell staff. Marshall and his colleagues, however, raised another important reservation—that a Harwell shrunk to one-third of its size simply would not be up to the very demanding business of nuclear energy research and development. So many questions remained unanswered about the fast

factor that nobody could possibly predict, when trouble struck, which of its vast array of techniques and talent would be needed

Marshall and his colleagues were vehemently opposed to either closure or a major reduction in strength As he put it in a paper published by the National Academy of Sciences last year "When a group of talented scientists and engineers have been brought together into a national laboratory and they have partially fulfilled their original mission, it seems to me unimaginative and wrong simply to disperse the ability national laboratories are a national asset, but they should be encouraged to change their orientation from time to time'

In other words, Harwell was seeking a new national mission to augment a diminishing role in nuclear fission The most obvious subject was nuclear fusion, but this had already been hived off to a new centre, the Culham Laboratory, while Marshall himself, once deeply into the physics of fusion, had turned to solid state physics because of frustration with the chaotic state of plasma physics in the mid-1960s

The mission conceived by Adams, Marshall and their colleagues was born of an awareness that "British scientists regularly produced good scientific ideas which led fairly rapidly to an improvement in the balance of payments of other countries but not of our own" (*The New Scientists*, OUP, 1971) At Harwell they had the skills, the equipment, and the proven ability to organise these facilities into effective problem-solving teams The mission they sought was the freedom to offer these facilities to industrial companies, on an exclusive basis, in an endeavour to help them to innovate

The Labour Government, well aware that Harwell was only the first of a number of national laboratories whose original missions were drawing to a close, looked kindly on Harwell's idea It even endorsed the proposal that Harwell should flout all traditions of British government-funded science and instead of making its research freely available to all-comers (as taxpayers) should work exclusively with chosen industrial partners With characteristic irreverence the idea was dubbed "the principle of maximum unfairness"

The difficulty, as Marshall records in *The New Scientists* was the "large number of arguments against the general idea, mostly drawn to our attention very forcibly by other people " Harwell's own attitude at the time was somewhat ambivalent, with many of the physicists and chemists opposed to the scheme, though the metallurgists, engineers, corrosion experts and so on were strongly in favour

Other opponents included industry itself, whose response was entirely unambiguous "Industry simply did not want us, and most people sought strongly to discourage us "

Marshall must take a major share of the credit for the success of the 'Harwell experiment' in which the portion of its income outside the Atomic Energy Vote has grown steadily to some £8 million last year, about 40% of the laboratory's budget

Marshall's industry-orientated research effort has, however, had its full share of disappointments and failures A prototype isotope-powered heart pacemaker failed in a patient A promising new method of desalinating sea water was turned down by the government as uneconomic when funds were sought for a demonstration plant Perhaps most disappointing of all was the decline and fall of carbon fibre

Last summer he shouldered the task of bringing the deductive logic of science to bear on the affairs of the new energy department In terms of influence the post had some obvious attractions, for the department is nominally responsible for an outlay on energy research and development which this year will total £120 million The post also provided a seat at the table of departmental scientific advisers counselling the Cabinet on scientific affairs

The obverse of the coin is that the research resources of the energy department are unquestionably undernourished Most of the £120 million is administered by the various energy industries and agencies, as the accompanying table shows As Marshall told the Select Committee on Science and Technology recently, his freedom for action in terms of research funds is restricted at present to a mere £200,000—the cash allocated last spring to set up the Energy Technology Support Unit at Harwell, which is appraising alternative energy options open to Britain

But as Chairman of ACORD, the Advisory Committee on Research and Development for the energy industries —traditionally an independent appointment but one Marshall insisted on taking himself—he can encourage a spirit of cooperation where once there was fierce competition, and of concern to conserve rather than to promote further use of particular fuels For the moment the emphasis is on technical services and what the application of research data already existing —perhaps garnered a decade ago—can do quickly to reduce energy consumption in industry

Outside ACORD, to which each of the state-owned energy industries will be submitting its annual report on research for appraisal this spring, the

Department of Energy is spending about £21 million in the current year on research contracts placed with Government and industrial laboratories Half of this sum is committed, however, to the Anglo-German-Dutch gas centrifuge project for uranium enrichment The only laboratory that came under the direct control of the department's Chief Scientist, namely the Safety in Mines Research Establishment, was transferred to the new Health and Safety Commission earlier this year

Several problems therefore loom large this spring for Dr Marshall First, he has a major part to play in preparing a paper for the Cabinet putting forward the case for a new phase in the development of the fast breeder reactor, far and away the most rewarding prospect in sight for research and development in energy conservation The new phase, however, will involve a sum of the magnitude of Britain's contribution to Concorde, for it must include a large scale demonstration power station using the sodium-cooled fast reactor

Second, he has to coordinate Britain's role in the energy research programme of the International Energy Agency which—largely, it is said, because of his own influence—blossomed abruptly in January with a series of proposals for multi-national ventures, with Britain taking the lead in coal technology

A third and possibly less tractable problem for Marshall is to create a research arm under his own control to the department's Offshore Supplies Office in Glasgow Only when thus equipped will the department feel competent to monitor what must surely be a rapidly burgeoning budget for offshore and seabed research and development contracts placed with other British laboratories

Fourth, he must strengthen his own scientific secretariat in the department, numbering merely 30 at present, and strongly orientated towards coal—a legacy of its origins in the erstwhile Ministry of Fuel and Power

A scientist on the Cabinet Office committee of departmental chief scientific advisers has remarked that Walter Marshall tends to raise eyebrows among his older and—in terms of Whitehall politics—much more experienced colleagues by starting his contributions "I don't know what you fellows think but at Harwell " Marshall is proud of the way he has rekindled the vitality of this research centre, transforming it into a brisk, businesslike organisation, second-to-none in the management of research projects Nobody would be very surprised if Walter Marshall now turned his top Harwell management loose on the problem of reshaping the nation's energy research and development effort

international news

In a move that will do little to enhance public confidence in environmental regulations and even less to restore public faith in technology, the Environmental Protection Agency (EPA) last week reluctantly decided to give automobile manufacturers at least another year in which to make further reductions in car exhaust emissions The agency really had little choice in the matter

The basis of the decision—which EPA Administrator Russell Train said last week is "the most unhappy decision that the agency has had to take since I have been here"—is relatively simple The catalytic converters which all American car makers have adopted to clean up exhaust pollutants may themselves pose a hazard to health, so the EPA has decided to see how serious the hazard may be before forcing even more widespread use of catalysts In short, although the catalysts seem to do a good job in oxidising hydrocarbons and carbon monoxide to less harmful compounds, they are also quite effective at oxidising sulphur dioxide to sulphuric acid, with the result that cars fitted with catalysts may be giving out harmful amounts of acid

The decision to put off enforcement of stricter regulations was politically painful because it now provides car

Car catalysts pose health problems

from Colin Norman, Washington

manufacturers and other industries with excellent propaganda material to use against any legislation which forces rapid introduction of clean-up technology When Congress belatedly forced the car companies to clean up exhaust emissions by putting a pistol to their heads in the shape of the Clean Air Act, the only technology available was the exhaust catalyst The car companies screamed that catalysts would be expensive, would increase gasoline consumption, and would simply be bad technology They begged for more time to develop other technologies, but Congress and the EPA decided that, on the basis of past performance, the car companies wouldn't use the time to develop other means of controlling exhaust emissions, and so forced them to use catalysts

As far as hydrocarbons, carbon monoxide and oxides of nitrogen are concerned, the catalysts have proved to be

extremely effective What's more, : spite of Detroit's warning to the co: trary, their introduction on many 197 model cars has even led to increase performance and efficiency Then can the sulphuric acid problem

It first came to light in the mi 1960s, but was disregarded as being 1 significant Then, in mid-1973 the prol lem was brought up again and give widespread publicity, and the EP, started a crash programme to dete: mine just how serious a hazard t health it might be The EPA found th; cars equipped with catalysts produce on average, 35 times more sulphuri acid per mile than cars without cats lysts Moreover, if an air pump is use to inject more air into the catalyst— device which would be required to mee stricter pollution control standards— then production of sulphuric aci would be about 70 times that of a ca without a catalyst

Although the amount of acid prc duced by automobiles would be only : tiny fraction of that produced by fac tories, the problem is that it would b concentrated along freeways and 11 cities

It wouldn't be so bad if there were : potential solution just around th corner, but there isn't None of th three possible solutions—removing sul phur from gasoline, putting a sulphu trap in the exhaust and improving cata lyst technology—provides a basis fo regulation, Train said last week I therefore seems at this stage that the only real chance of removing harmfu pollutants from car exhausts withou causing another health problem is fo the car companies to go for a com pletely different engine design, such a: the stratified charge engine But since Detroit produces 10 million cars a year it would be many years before the entire production line could be converted to a new technology

At least total amounts of automobile pollutants spewed into the atmosphere will continue to decline, even with the regulations frozen at this year's level, because older, dirtier cars will be replaced with cars equipped with 1975-level control devices But, since the fight over automobile pollution has been widely publicised, and because Congress and the EPA staked their hopes on the catalytic converter, the utter shambles that now reigns will be greeted with glee not only in Detroit but in a good many other corporate board rooms as well ☐

THE US Fish and Wildlife Service believes it has found a cheap and effective method for removing the potent teratogen dioxin from the herbicide 2,4,5-T If so, it would remove some, though not all, of the opposition to use of the herbicide in the United States, and it would also provide a solution to the problem of what to do with the 2 3 million gallons of dioxin-contaminated 2,4,5-T left over from the Vietnam war

The process is extremely simple According to an announcement from the US Department of Interior, all that is required is to filter the solution through coconut charcoal and to rinse the charcoal with acetone Tests carried out at the Fish and Wildlife Service laboratory at Columbia, Missouri, have shown that more than 99% of the dioxin in 2,4,5-T is removed by the method, and the government has applied for a patent for the process

Although removal of dioxin from 2,4,5-T would make the herbicide much safer, there is considerable doubt about whether or not 2,4,5-T itself is terato-

genic The herbicide is therefore still unlikely to get a completely clean bill of health from its critics

● After that embarrassing incident last year when President Ford had to withdraw the nomination of Andrew Gibson as head of the Federal Energy Agency when it became known that Gibson was drawing a large salary from the oil industry, Presidential appointees have been subjected to a thorough investigation before their names are sent to the Senate for confirmation Last week, however, Ford announced that four people have passed the test and are being nominated for top science posts They are Robert W Fri, to be Deputy Director of the Energy Research and Development Administration (ERDA), James L Liverman, to be Assistant Administrator of the ERDA for the environment, John Teem to be an Assistant Administrator of the ERDA for advanced energy systems, and Richard C Atkinson to be Deputy Director of the National Science Foundation

THE Medical Research Council is to set up a new unit for research in clinical oncology and radiotherapeutics at Cambridge, at the same time, the Cancer Research Campaign has provided an endowment of £275,000 to establish a new university chair of clinical oncology Professor Norman Montague Bleehen has been appointed Honorary Director of the MRC Unit and Professor of Clinical Oncology He will take up both posts at the beginning of the academic year in October The unit officially starts operation in October and will be provisionally housed at the new Addenbrooke's Hospital It is hoped that purpose-built accommodation can be provided within five years Professor Bleehen is at present Professor of Radiotherapy at the Middlesex Hospital Under his direction, the new unit's general aim will be to improve the results of current methods for the treatment of cancer and to develop improved methods of measuring the clinical and biological response of tumours to treatment The programme will include investigations on lung cancer, rectal cancer and osteosarcoma, with particular reference to occult metastatic disease Staff at the new unit will collaborate closely with other workers there with oncological interests In particular, it will provide a clinical link for the laboratory research now being carried out in Cambridge by a Tumour Biology Group led by Dr Sydney Brenner at the Laboratory of Molecular Biology

The new chair in clinical oncology is the fourth to be funded by the Cancer Research Campaign Chairs have already been set up at the Institute for Cancer Research in London and at the universities of Manchester and Glasgow A fifth is to be established shortly at the University of Southampton, and when complete the scheme will have cost about £3 million The Cancer Research Campaign is the largest supporter of research into cancer, including leukaemia, in the UK and in 1974 awarded grants totalling more than £4 5 million

● In this year's list of prizes and medals awarded by the Institute of Physics, afficionados of the entertaining experimental demonstrations at the Royal Institution lectures will be glad to see the award of the Bragg Medal and Prize to Mr W A Coates "for his contribution to education through the design and execution of demonstrations illustrating the many lectures held at the Royal Institution" Mr Coates first joined the Royal Institution in 1948 as a technical research assistant on X-ray diffraction experiments and became Senior Experimental Officer in charge of preparation and production of teaching demonstrations under the directorship of Sir Lawrence Bragg

After more than 10 years organising the demonstrations, which Mr Coates admits he embarked on with some reluctance when Sir Lawrence asked him to help with the lectures for schools started in the late 1950s, Mr Coates still thoroughly enjoys a job which can have its unexpected hazards Recently, after setting up a demonstration for measuring the potential of an electric eel, an ugly customer which can give a shock up to 400 volts, he returned from a meal to find the tank empty and the eel gone Luckily it had landed on a rubber mat nearby and so was returned to its tank with no further mishap, the demonstration was a complete success

Round Britain

● The publication this week of the latest annual report of the Science Arm of the Agricultural Development and Advisory Service (ADAS) of the Ministry of Agriculture (HMSO, £5 50) should prove a good reference book for agricultural research scientists looking for sources of useful but often unpublished data, and of problems which would repay further research

In their role as scientific troubleshooters to the agricultural industry ADAS has amassed a unique collection of field and experimental data (which of its nature is usually not publishable in the conventional scientific literature) on a wide variety of agricultural problems ranging from heavy metal contamination of sewage sludges used as fertilisers and water pollution by agricultural wastes, to the optimum feed formulations for cattle As well as highlighting problems in need of further research, such data will prove invaluable in drafting pollution legislation, for example

Much of this work had previously been hidden in internal reports but with the formation of ADAS in 1971 from several of the ministry's advisory services, it was felt that the work could be usefully brought to the attention of a wider audience Formal links between ADAS and the Agricultural Research Council have also been strengthened recently with the formation of the Joint Consultative Organisation for Agricultural Research Policy, on which ADAS is represented

Britain's entry into the EEC has also involved ADAS in the collection and evaluation of technical information and advice for the negotiating teams in Brussels trying to harmonise the many regulations concerning agricultural practice and produce throughout the community—for example those dealing with the antibiotic content of animal feeding stuffs and the tests used to determine the quality of milk and milk products The service has also been involved in the analytical tests to determine standards of produce submitted to the Intervention Board for Agricultural Produce

● Professor Jack Meadows, of the University of Leicester, has been given a £16,000 grant by the British Library to study how scientific ideas get to the mass media and how they are used by television, radio, newspapers and magazines Part of the grant will be used for research into the way in which journals monitor research papers and why some work is rejected and some accepted in a situation in which the journal is receiving more 'good' papers than it can publish

This work stems from a study in the United States by Merton and Zuckermann, who monitored the rejection rate of the leading specialised journals over a range of subjects and found a definite correlation with subject Journals of the physical sciences had lower rejection rates compared with biological journals, and the rate was even higher for psychology and learned journals of the humanities The American workers also found that the rejection rate was positively correlated with the degree of disagreement among the referees

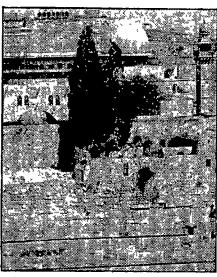
Professor Meadows and his team hope to extend this type of investigation into the British system, as the influences at work may well be different from those in the United States He hopes to find out in detail what happens in the refereeing process, and whether some of the myths surrounding refereeing are in fact justified Needless to say this type of investigation must be organised so that the confidentiality of the refereeing system is maintained In tune with the times, the team will also investigate how the economic situation, as reflected in decreases in the number of journal pages, has affected the refereeing process by perhaps making it more stringent

● Much head-scratching and pen-chewing in Cambridge these days Professor J W Linnett, Vice-Chancellor and Professor of Physical Chemistry, is worried that university research is being poor-mouthed by certain 'ladies and gentlemen' So he has circularised departments to enquire of any "useful research of clear value in the relatively short term" If the right sort of stuff comes up he then intends to alert ministers, MPs, newspapers and industrialists to the merits of the place

LAST year Israeli farmers produced 78% of the foodstuffs consumed in Israel, as well as exporting enough agricultural products to pay for most food imports Now, with the active assistance of local researchers, they are attempting to reduce further Israel's dependence on imported food products, particularly commodities like wheat and sugar which have gone up in price by hundreds of per cent in recent years

Research has already been a key factor in raising the average yield of wheat from some 900 pounds an acre in 1950-55 to more than 1,600 pounds an acre today, with yields of 6,000 pounds an acre common in more fertile parts of the country Current studies could well increase output even more

Some of the most interesting work is being carried out by Moshe Feldman and Dan Atsmon, of the Weizmann Institute, who are using sophisticated cytogenetic techniques in an attempt to transfer valuable characteristics from native Israeli wild wheat to standard wheat varieties being grown here and elsewhere

Since this area, long known as the Fertile Crescent, is the cradle of wheat farming, it naturally abounds in wild varieties And although these are not satisfactory for modern farming themselves, they nevertheless manifest some very interesting characteristics worth "stealing"


Drs Feldman and Atsmon are paying special attention to a species from the Negev Desert (*Triticum longissimum*), which is at home in an area with as little as 25 cm of rainfall annually, tolerates brackish water, and grows and matures quickly—so much so that, were cultivated wheat to ripen as fast, it would be possible to plant and harvest two (irrigated) crops a year

The Weizmann scientists have isolated seven individual chromosomes of the Negev wild wheat, including the one responsible for its early maturation Now they are attempting to incorporate selectively these valuable chromosomes into standard wheat varieties, which should make it possible to increase yields in well watered areas, and also permit wheat to be grown in other areas where sparse rainfall has so far prevented its cultivation

More land will likewise be given over to the growing of sugar beet, while research continues in an attempt to develop other economically viable sources of sugar and sugar substitutes Ministry of Agriculture studies have indicated, for example, that at present price levels it is worth making sugar from locally grown sorghum

Meanwhile scientists at Ben-Gurion University of the Negev, led by Pro-

fessor Jaime Wisniak, are concentrating on sugar substitutes, including xylitol So far produced on a commercial basis only in Japan, xylitol is derived from vegetable residues such as cotton seed hulls, corn and other seeds containing cellulose It has the same crystalline form as sugar and is actually 10% sweeter Since it does not require insulin for metabolisation of body material, it can safely be used by

Letter from Israel

from Nechemia Meyers

Western Wall   to weed or not to weed?

diabetics Wisniak proposes that Israel produce xylitol on a large enough scale to meet domestic requirements and to allow for exports

● Israeli scientists studying plant life are involved not only in solving the country's food problems but also some of its religious problems Namely, they are being asked by religious authorities whether or not weeds should be pulled out of the sacred Western Wall in Jerusalem's Old City

Diametrically opposed rulings have been issued by Israel's constantly feuding Chief Rabbis, Shlomo Goren and Ovadia Yosef Ashkenazic Chief Rabbi Goren declared that the plants could not be pulled out since they are symbolic of the destruction of the Second Temple (in 70 AD) and the longing of Israel for redemption Sephardic Chief Rabbi Yosef ruled that they could be pulled out, particularly as they might crack the Herodian-period stones

The man who asked the Chief Rabbis for their opinions in the first place, Rabbi Dov Perla of the Religious Affairs Ministry, has now turned to a botanist to determine—for the first time in the Wall's 1,900-year history— whether or not the weeds are likely to

cause damage

● Religion, or more properly religious folklore, provided the name for Israel's largest locally built computer, the Weizmann Institute's Golem The original Golem was a legendary automaton created by a famous Prague rabbi in the Middle Ages and, like Mary Shelley's Frankenstein, it eventually turned on its creator

The legend came to mind last week when 30,000 Israeli primary school teachers declared what may have been the world's first strike against a computer Their one-day walkout was called to protest about difficulties with the Ministry of Education's computer which have caused long delays in the payment of salaries for the past 16 months

Computing teachers' salaries does present special problems, as 18,000 changes must be taken into consideration every month But these problems could easily have been solved if it had not been for the human factor

Trouble began in the Ministry of Education's Data Processing Department some four years ago when it became clear that the rented IBM 360/40 then being used to calculate salaries was no longer able to handle the work load Department employees suggested that it be replaced by a higher capacity IBM machine, which, coming from the same company, would ease conversion problems The ministry decided instead to purchase a Burroughs computer because it was $250,000 cheaper and because, according to benchmark tests carried out in the USA, it was able to perform tasks required by the ministry about 15% faster

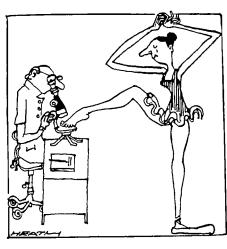
Preparations for conversion to a Burroughs computer were carried out in the department while regular work was done on the old IBM Difficulties arose, but only became really serious when call-ups because of the Yom Kippur War took away 80% of the data processors By the time they returned there was near chaos in the salary section, prompting employees to argue that only the introduction of a new IBM could save the situation When the ministry remained unmoved, 46 of the 47 people in the Data Processing Department handed in their resignations and, according to Education Ministry Director General Elad Peled, left without passing on vital information about tape codes for salary calculations to their replacements (provided by the local representatives of the Burroughs Company)

Peled charged his former subordinates with sabotage, they, in turn, charged him with libel But all this is of little interest to teachers, who merely want their salaries on time

'lood studies rom NERC

om Angela Croome

'HE engineer designing a dam or a eservoir, or the city planner contem- lating urban development on river mbankment or flood-plain is in the ands of the hydrologist and to some xtent the meteorologist Britain's Insti- ution of Civil Engineers (ICE) grasped his fact in the 1930s after a major re- iew following the last failure of a dam n Britain—happily now 50 years ago which is something of a record) The nstitution has pressed ever since for a omprehensive applicable prognostic pproach enabling engineers to design vith confidence a structure which vould last Britain's civil engineers btained this document last week in he form of the Natural Environment Research Council's *Flood Studies Re- ort*

A draft code of practice closely ssociated with this report is coming ut for discussion within a few weeks, nd from some time in 1976, when dopted in final form, any civil engineer n Britain who does not follow it will e guilty of professional negligence In May the ICE is calling a meeting in London to examine in detail the report nd the code of practice, their validity, nd their relevance outside Britain


The influence of the report is likely o be great and much more widespread han its original terms of reference might suggest It is the most compre- hensive attempt that has been made anywhere to tackle the problem of flood estimation and, in the opinion of the International Commission on Large Dams, it is "head and shoulders" above all others The ICE is already prepared to say that as a result of its findings many flood-protection schemes will have to be revised

The study has involved nearly five years of work by a multidisciplinary team based on and led by a staff of 15 recruited by the NERC Institute of Hydrology, and assisted by a six-man group of Meteorological Office scien- tists The statistical analysis of cor- related rainfall and runoff records on the widest possible scale forms the core of the study This has involved collect- ing an archive of 9,300 'station-years' of records (from the 1,200 stream- gauges in the UK) plus a further 1,700 'station-years' from 110 Irish gauge- stations Records from 6,000 rainfall stations were also included

The result in practical terms is that for any area of 500 km² in Britain, a reliable estimate of the mean annual flood level and its frequency can be obtained (In other terms, the report amounts to the most comprehensive

available textbook on hydrological sta- tistics—for all the data is tabulated there as well as the mathematical rela- tionships derived from them)

Basically, there are two methods now available Where there are gauge- station records for a given river basin, a statistical method is presented enab- ling the practitioner to get specific answers to his questions—how high is the maximum flood level he must build for over, say, 10,100 or 1,000 years, and how often is it reached This can be derived either from records of the annual maximum for the area or from data on the peaks above a threshold level Where only rainfall records exist —that is, in an ungauged river basin— the run-off characteristics of a site can be estimated, given information on four characteristics of the catchment, namely, slope, soil, land-use and area As rainfall records are usually more extensive and go back further, the sec- ond method may be more easily applic- able outside Britain but it can only be reliably applied in other cool or tem- perate regions □

THE results of a 15-year survey, car- ried out on more than 100 pupils of the Kiev School of Choreography, has revealed significant modifications in the toe structure of ballet students, these are put down to the increased loads imposed on the toes when dancing on the point or demi-pointe The study, carried out by biologist Vladislav Peli- penko and based on regular X-rays of the toes during the course of 15 years of training and dancing, showed that within a short time the bones undergo significant thickening of the outer layers and restructuring of the inner layers On the basis of these measure- ments, Pelipenko has compiled tables which, he claims, will provide a basis for the selection of new pupils and a means of forecasting their future per- formance The results of these experi- ments, he suggests, can also be applied to draw up training schedules for gym- nasts and athletes, who also experience unusually large loads on the toes □

Science writers and government policy

from David Spurgeon, Ottawa

PROFESSIONAL science writers and scientists co-exist for the most part under conditions of uneasy truce Thus it is refreshing when one side finds good things to say about the other Just such an occasion was the fifth annual science writing seminar of the Cana- dian Science Writers' Association, held on February 24 and 25 at the Univer- sity of Toronto The welcome by Dr George Connell, Vice-President Re- search and Planning at the university, was positively fulsome

The reason, basically, was that Dr Connell felt that "active and well in- formed men and women of the press, radio and television" were to a large extent responsible for influencing the federal government to reverse the re- cent downward trend in research funding

"For the first time in six years", said Dr Connell, "the levels of support through the [research] councils will balance inflation "

Dr Connell recalled that the buying power of the average grant from the National Research Council (NRC) in the physical sciences, the biological sciences (excluding health sciences) and the engineering sciences decreased by 7% between 1970 and 1974

"Early in 1974 a group of medical scientists and well informed laymen decided to present to the public an account of the benefits of medical re- search and the difficulties which have impeded its progress," Dr Connell said "The response of the press, radio and television to this initiative was remark- able in Toronto the daily newspapers provided coverage which was remark- able both for its quality and quantity The activity in other cities across the country was also notable "

The outcome, the vice-president said, was that, in the main estimates tabled the week before the seminar, the gov- ernment proposed to spend $48 4 million through the Medical Research Council (a 13% increase over the 1974-75 esti- mates), NRC estimates for scholarships and grants increased from $69 3 million (1974-75) to $81 7 million (1975-76) and the Canada Council's increase was from $23 9 million to $27 7 million

The usual discussion took place of the difficulties of understanding and translating scientific jargon, but it was left to a French Canadian writer to put things in a suitably Canadian perspec- tive he said that being a French speaker was a much bigger communi- cation problem than all the rest, be- cause French-speaking scientists in Canada are so hard to find □

correspondence

Nutritional landmark

SIR,—Reports prepared by expert committees on specific areas of nutrition are frequently issued, notably by the Food and Agricultural Organisation and the World Health Organisation It is, however, an event of significance when a comprehensive survey of food and nutrition research in a single country with a strong tradition of scientific and medical investigation is assembled by a large team representative of the available experts It is indeed a considerable achievement to have synthesised such a readable report from the documents provided by the various working parties, to one of which I was a minor and temporary contributor The product is a landmark document, which appears at a time when the bridge between basic research and applied research in the national interest must be strengthened in the interests of survival Food and nutrition research needs to attract original minds trained in the basic sciences This document should provide the points of contact It is thus entirely proper that the committee responsible for assembling the report should have included Sir Douglas Black, Chief Scientist to the Department of Health and Social Security and responsible in Britain for implementing contracts in areas of applied research

I write this comment because a petulant and partly irrelevant review appeared in *Nature* (January 10) castigating the report because of insufficient emphasis on social nutrition, and ridiculing the priority areas for research identified in the report On the contrary, the report correctly identifies and summarises current knowledge in numerous areas of nutritional research that are of great importance to human health and survival the role of nutrition in vascular disease, diet and cancer, dietary fibre and the spectrum of diseases in a population, the aetiology of osteoporosis, nutritional aspects of renal disease, to name some in only one section of the report The current problems in food and nutrition research are numerous, important and challenging Further research into the areas identified in this comprehensive document should allow governments to plan research strategies, to test new food sources and to monitor the population more efficiently Finally, the present disreputable status of nutrition research among basic scientists and the medical profession will also be materially mitigated by the vigorous well-founded directions indicated in the report

Re-use of vials

SIR,—In the February 27 issue, Professor Born rightly drew attention to the need to minimise waste in laboratories and cited as a specific example the destruction of scintillation vials after being used only once It may be of general interest, therefore, that in this department we have for a number of years successfully re-used vials without risking contamination or any of the other problems which Professor Born mentioned The procedure we have adopted involves placing the radioactive sample and scintillation fluid in an ordinary $5\,cm \times 1\,2\,cm$ diameter specimen tube that is inserted into the vial for counting This simple method has the following advantages (1) the vials themselves are not contaminated, (2) the volume of scintillation fluid is only 2 ml, thus reducing costs, (3) the specimen tubes are very much cheaper than the scintillation vials They may be either discarded or used for other purposes after normal cleaning

The method works particularly well for non-aqueous samples—for example, materials on membrane filters or papers —since in these cases there is no reduction in either the counting efficiency or the amount of labelled material used in the assay

King's College, London

Science and technology

SIR,—In his paper on the changing relationship between science and technology (August 23, 1974) Langrish quotes evidence from previous citation studies which, he asserts, support his views that "British university research has little impact on British industry" We wish to challenge the view that generalisations can be made across all fields of scientific endeavour on the usefulness or otherwise of university research to industry on the basis of the evidence provided by citation analysis

On the assumption that industrial reviewers will cite any universit research which they consider to be c relevance to industrial activity, Langris chose seven review articles written b British industrial chemists in the 196 volume of *Reports on the Progress c Applied Chemistry*, and found that th papers which the reviewers considere most relevant to technological develop ments in the seven areas were largel of non-university origin The area chosen were phenolic resins, micro biological techniques in manufacture water treatment, plastics, polyolefins synthetic detergents and poultry an eggs In only one area (microbiologica techniques) was the influence of uni versity research dominant, and thi indicated to the author the importanc of the universities in generating nev techniques for industrial uptake

We suggest, however, that a citatior study such as this fails to take intc account the fact that it is much more likely that there will be university research activity in the area of micro biological techniques, for example, than in water treatment, and that there may be certain major areas of scientific enquiry in which the institutional sources of citations are quite different from the sources found in the disparate subject-areas used as samples by Langrish In particular, we suggest that the conclusions reached in citation studies of the physical sciences do not have general validity and, in order to demonstrate this, we carried out a study of the institutional sources of citations in five biologically oriented review articles in *Reports on the Progress of Applied Chemistry* All the articles were concerned with well established areas of scientific enquiry, and showed that in terms of citations, the universities outstripped every other sector

One should be wary of generalisations about the industrial utility of university research which rely on evidence from citation data Langrish has stressed the implications of his citation data for policy makers in government and industry, and the fact that we have been able to obtain results which differ so widely from his raises serious doubts as to the validity of the technique of citation analysis in the determination of the relationship between science and technology Policy decisions cannot and should not be made on the basis of such dubious evidence

Viruses associated with human leukaemia

rom Robin Weiss

'HREE new reports strengthen the pinion that there is a C-type virus ssociated with human leukaemias /Iak and his colleagues at the)ntario Cancer Institute (*Proc natn lcad Sci U S A*, **72**, 623, 1975, and **1**, 4336, 1974) describe the appearance f virus-like particles in medium from hort-term cultures of leukaemic bone narrow cells Cultures of bone mar-ow from normal individuals did not elease particles, but cultures from both ymphocytic and myelocytic leukaemic patients did so, when the bone marrow vas taken either at blast cell crisis or n remission Mak *et al* have not been ble to demonstrate budding particles, lthough the incorporation of tritiated iridine into the RNA of the particles ndicates that viral RNA synthesis)ccurs in culture The virus-like par-icles have the buoyant density, reverse ranscriptase and 60–70S RNA typical)f animal C-type viruses, and mole-cular hybridisation studies indicate that it is related to woolly monkey ymphosarcoma virus and to Rauscher virus In contrast to their bone marrow cultures, Mak *et al* found that cultures of peripheral white blood cells taken from leukaemic patients do not release virus-like particles The Toronto group seem however to be unaware of an earlier report by Kotler *et al* (*Nature new Biol*, **244**, 197, 1973) that white blood cells from patients with lymphocytic leukaemia can be induced to release very similar particles when cultivated in medium lacking arginine

Gallagher and Gallo at the US National Cancer Institute (*Science*, **187**, 350, 1975) describe the production of virus from cultures of three myelo-blastic cell lines from the peripheral blood of a patient with acute myelo-genous leukaemia For the first time these authors show really convincing electron micrographs of C-type virus particles, including budding forms The virus found in the medium of the myeloblast cultures possesses all the physical and chemical properties that characterise C-type viruses, and the reverse transcriptase activity is speci-fically inhibited by antibodies prepared against the reverse transcriptases of gibbon and woolly monkey viruses

Gallagher and Gallo did not observe virus production in white blood cells freshly isolated from leukaemic patients, but on prolonged cultivation of the myeloblasts from several cases of acute myelogenous leukaemia, virus began to be released from cultures derived from one 61-year-old patient Perhaps the most notable advance is not the appearance of the virus itself, but is the ability to maintain long-term, exponentially proliferating cul-tures of myeloblasts The growth of the myeloblasts depends on a conditioning factor produced by a human embryo cell strain Gallagher and Gallo believe that the conditioning factor, which has not yet been characterised, is neces-sary both for myeloblast growth and virus release They are confident that the virus arises directly from the leukaemic cells, since neither virus nor viral components were detectable in the embryo cell strain or the filtered, onditioned medium

Scherr and Todaro at the US National Cancer Institute (*Science*, **187**, 855, 1975), using material generously provided by Gallo and Gallagher, now report that antigens related to a major structural protein (p30) of the woolly monkey and gibbon C-type viruses are present in the white blood cells of five patients with acute leukaemia

While these new findings mark a significant advance in the search for human leukaemia viruses they come as little surprise Over the last three years evidence has steadily mounted, largely from Spiegelman's and Gallo's laboratories, that a viral entity is associated with human leukaemic cells A DNA polymerase with the properties of viral reverse transcriptase was regularly detected in human leukaemic cells (*Nature new Biol*, **240**, 67 and 72, 1972) The enzyme was associated with high molecular weight RNA in a cytoplasmic particle but no complete, cell-free virus particle could be detected Later, Todaro, Gallo and Gallagher (*Nature*, **244**, 26, 1973, *Proc natn Acad Sci U S A*, **71**, 1309, 1974) showed that the enzyme activity of the cytoplasmic 'particles' was specifically inhibited by antisera raised against the reverse transcriptases of gibbon and woolly monkey C-type viruses Hybridi-sation studies by Baxt, Spiegelman and

colleagues (*Proc natn Acad Sci USA*, **69**, 3737, 1972, **70**, 2629, 1973 and **71**, 2853, 1974) indicated that DNA complementary to the particulate RNA was present in human leukaemic cells but was not detectable in normal white blood cells, not even in two cases of identical twins to the leukaemic patients Gallo's group (*Proc natn Acad Sci U S A*, **70**, 3219, 1973 and **71**, 3177, 1974) have compared the homology of the 'viral' RNA of human leukaemic cells to a variety of animal C-type viruses and have found that it is most closely related to the woolly monkey lymphoma–sarcoma virus complex

It was therefore predictable that the human viral particles isolated by Gallagher and Gallo and by Mak *et al* would prove to be related to the woolly monkey virus, the human leukaemic p30 proteins described by Scherr and Todaro are indistinguishable in a radioimmune competition assay from the p30 of the woolly monkey virus

Oncologists have become justifiably sceptical of new claims for the isola-tion of human tumour viruses, since some highly publicised announcements of human viruses in the past were found on subsequent analysis to be contaminating animal viruses Clearly it is going to be difficult to prove that these latest isolates are not a result of contamination with laboratory stocks of woolly monkey virus Nevertheless, there are several telling points against contamination First, it is clear that freshly isolated human leukaemic cells that have not been maintained in culture carry the reverse transcriptase, p30 protein, and some RNA sequences related to the woolly monkey virus Second, Mak's virus-releasing bone marrow cells were all short-term cul-tures maintained in a laboratory where woolly monkey virus was not pro-pagated Third, the virus produced by Gallagher's long-term cultures appeared in three sublines that were maintained separately from the first passage on-wards But it does seem strange that a human virus should have such a close affinity to a virus complex isolated from a New World monkey To my mind, it is more likely that at least one component of the woolly monkey virus complex was acquired from man,

for it represents a single isolate from a pet monkey (Theilen *et al*, *J natn Cancer Inst*, **47**, 881, 1971) Perhaps the long sought human virus has been in our laboratories for the past four years

The human leukaemia 'virus' does not seem to be endogenous because homologous proviral nucleotide sequences have not been detected in DNA extracted from normal human tissues, not even in Baxt's identical twin studies referred to already There is however some recent evidence for an endogenous human virus related to RD-114 and baboon viruses (Strand and August, *J Virol*, **14**, 1584, 1974, Scherr and Todaro, *Proc natn Acad Sci U S A*, **71**, 4703, 1974) This virus does not seem to be closely related to the woolly monkey virus and its expression is not particularly associated with leukaemia or with other neoplasms, but rather with systemic lupus erythematosus In cats, for instance, the infectious, leukaemia-causing virus has very little homology with the endogenous viral genome Could a human leukaemia, therefore,

be acquired by infection, as in cats and chickens?

There is no epidemiological evidence that leukaemia is contagious, except for one recent report by Schimff *et al* (*Lancet*, **i**, 124, 1975) of possible clusters in incidence of leukaemia of various kinds by social contact in a small rural community in West Virginia If, however, leukaemia were a rare and late consequence of a very widespread and common infection it would be difficult to obtain epidemiological evidence for infection Indeed this was the case with feline leukaemia before the virus was isolated and exploited as a serological tool In concluding their paper, Scherr and Todaro state that "the isolation of complete C-type viruses from human leukaemic cells should greatly assist in evaluating their etiologic role in the disease" A number of laboratories are now attempting to propagate the viruses or particles isolated by Mak and by Gallagher and Gallo while further, independent isolates are eagerly awaited

accumulate Straight chain acids of th type have been found by Barley *et a* in rat glial cells cultured in vitami B_{12}-deficient medium (*J biol Chem* **247**, 4270, 1972) More recently simile abnormal fatty acids together with branched chain 17-carbon version wei found in autopsy tissue from a chi: who had extremely high levels of urii ary methylmalonic acid probably as result of a congenital inability to coi vert vitamin B_{12} into its coenzyme forn (Kishimoto *et al*, *J Lipid Res*, **14**, 6! 1973) And, most exciting, Frenkel h; demonstrated 15- and 17-carbon fati acids in peripheral nerve biopsies froi cases of pernicious anaemia (*J cli; Invest*, **52**, 1237, 1973)

It is probable that the straight-chai fatty acids are formed when propriony coenzyme A substitutes for acetyl cc enzyme A as a substrate for fatty aci synthetase and the branched-chain fatt acids are made when methylmalony coenzyme A substitutes for malony coenzyme A The big question tha remains is whether the accumulate abnormal fatty acids are really th cause of the neural lesion associate with vitamin B_{12} deficiency and if sc how? Even the more impressive of th above studies have their shortcoming; How closely do cultured rat glial cell really relate to human spinal cord ii *vivo*, particularly considering that th rat does not develop neurologica problems when depleted of vitamin B_{12}' Why do children with congenita methylmalonylaciduria seldom, if ever exhibit the same neurological lesions a: in pernicious anaemia? And are th abnormal fatty acids found in the peri pheral nerves in pernicious anaemi also found in the spinal cord where th demyelination occurs? Nevertheless th similarity of the findings in each stud are impressive enough for the prob lems to be pursued The availability o the bat as a model for the neurologica changes of human vitamin B_{12} defi ciency should considerably assist the pursuit

For those who cannot work with bat: there are always bugs Work continue: apace on the metabolism of vitamir B_{12} in bacteria, if for no other reasor than the pious hope that there are un discovered vitamin B_{12}-dependent en zymes which are essential for the normal functioning not only of bacteria but of man as well Thus methionine synthetase, the only known vitamin B_{12}-dependent mammalian enzyme apart from methylmalonyl-CoA mutase, was discovered in *Escherichia coli* But it should not be forgotten that ribonucleo tide reductase, found in *Lactobacillus leichmann* as a vitamin B_{12} requiring enzyme, was at one time the great white hope for the biochemical basis of the megaloblastic anaemia of human vita min B_{12} deficiency Although the en-

Vitamin B₁₂ in bats and bugs

by Peter Newmark

THE neurological lesion which often accompanies human pernicious anaemia has no certain biochemical explanation One of the hindrances to progress has been the lack of a suitable animal model Though vitamin B_{12} deficiency (the cause of pernicious anaemia) results in both megaloblastic anaemia and demyelination of the spinal cord in humans, no common experimental animal placed on a vitamin B_{12} deficient diet has shown a consistent neurological lesion comparable to that in man But according to the report by Green *et al* in this issue of *Nature* (page 148) the Egyptian fruit bat may fill this gap

The success of Green *et al* may have had its origin in the natural diet of the bats This is vegetarian and therefore ostensibly devoid of vitamin B_{12} Green *et al* suggest that wild bats obtain the vitamin by consuming both stagnant water and insects contaminating the dietary fruit Both sources could be excluded in the laboratory diet of peeled fruit and tap water Within 7 months the bats had difficulty in climbing and flying associated with histological changes in the spinal cord reminiscent of the demyelination seen in human vitamin B_{12} deficiency

If this model fulfils its promise it will have appeared at an opportune moment for exploitation because recent evidence has at last suggested a plausible bio-chemical link between vitamin B_{12} deficiency and demyelination The link

is based on the requirement of a vitamin B_{12} coenzyme for methylmalonyl-CoA mutase and the consequent accumulation of methylmalonyl coenzyme A in vitamin B_{12}-deficient tissues Excessive methylmalonyl coenzyme A, and its precursor propionyl coenzyme A, could interfere with the normal metabolism of the fatty acids of the myelin sheath, resulting ultimately in demyelination The evidence that now makes this a distinct possibility is several fold

Clearly there is some rebalancing in the fatty acid metabolising enzymes of vitamin B_{12}-deficient tissues Frenkel *et al* (*J biol Chem*, **248**, 7540, 1973) have demonstrated increased activities of both acetyl-CoA carboxylase and fatty acid synthetase in the liver of vita-min B_{12} deficient rats, possibly in res-ponse to the inhibition of both enzymes by methylmalonyl coenzyme A The increase, at least of fatty acid synthe-tase, seems to be the net result of markedly increased synthesis of the enzyme together with a less dramatic enhancement of its degradation (Frenkel *et al*, *Archs Biochem Biophys*, **162**, 607, 1974) It is not, however, altogether obvious how to translate such changes into likely effects on the neural tissue

Much more impressive therefore have been demonstrations of accumulated abnormal fatty acids in neural tissue accompanying vitamin B_{12} deficiency In particular it is 15-carbon and 17-carbon saturated fatty acids that

zyme is not confined to *Lactobacillus* (Hamilton, *J biol Chem*, **249**, 4428, 1974), there is now little doubt that in mammalian tissues it is replaced by a vitamin B₁₂-independent version

Ethanolamine deaminase is indubitably not a mammalian enzyme It is found in clostridial bacteria, is vitamin B₁₂ dependent and has been studied in great detail by Babior (for example *J biol Chem*, **249**, 4537, 1974) Chang and Chang provide evidence on page 150 of this issue for the presence of the same enzyme in *Salmonella typhimurium* and perhaps also in other enteric bacteria The enzyme, like the clostridial one, is probably induced as a response to the supply of ethanolamine as the sole source of carbon and nitrogen together with vitamin B₁₂ Exactly why these bacteria should have the potential to grow on such an unnatural duo of nutrients is puzzling

Hormonal control of spermatogenesis

from R V Short

IN reviewing the hormonal control of mammalian spermatogenesis, Steinberger commented that "knowledge of the biochemical parameters of the hormonal action on spermatogenesis is too meagre even for a limited attempt to formulate a working hypothesis" (*Physiol Rev*, **51**, 1, 1971) Research so often seems to be at a standstill, that it is refreshing to record a number of important advances in our understanding of spermatogenesis in the last four years

There is now growing evidence from clinical (Franchimont *et al*, *J clin Endocr*, **34**, 1003, 1972, De Kretser *et al*, *J clin Endocr*, **38**, 787, 1974) and laboratory studies (Setchell *et al*, *J Endocr*, **62**, 675, 1974) that the pituitary gland is somehow aware of the number of spermatozoa that the testis is producing "Inhibin", a substance first postulated by McCullogh in 1932 (*Science*, **76**, 19, 1932), really seems to exist It is apparently produced by the germinal cells of the testis, and acts centrally to suppress the secretion of follicle stimulating hormone by the pituitary gland A number of laboratories throughout the world are actively working on the purification and identification of this new testicular hormone, and success seems near at hand

We are also beginning to get a clearer idea of the role of the Sertoli cells in the control of spermatogenesis These cells, which line the seminiferous tubules of the testis, are in intimate association with the germ cell line at all stages of their development, from spermatogonia to spermatozoa This close proximity suggests that there could be an important functional interrelationship between germinal and somatic cells, but hitherto we have lacked any biochemical understanding of the nature of this relationship Thanks to the collaborative work between Drs Hansson (Oslo), Ritzen (Stockholm) and French (Chapel Hill, North Carolina), we can now begin to understand exactly what is happening

It seems that the Sertoli cell is stimulated by follicle stimulating hormone to secrete an androgen-binding protein with a high affinity for testosterone and its biologically active metabolite, dihydrotestosterone (*Nature new Biol*, **246**, 56, 1973, *Nature*, **250**, 387, 1974) As Hansson and his colleagues point out in this issue of *Nature* (page 145), testicular androgens are known to be the principal stimulus for spermatogenesis, they seem to be required for almost all the stages of meiotic division (Steinberger, *Physiol Rev*, **51**, 1, 1971) In normal circumstances, luteinising hormone secreted by the pituitary gland acts on the interstitial or Leydig cells of the testis to induce testosterone secretion Though much of this hormone then enters the systemic circulation, the intratubular androgen binding protein may be a vital link in the chain, enabling some hormone to be captured and concentrated within the lumen of the seminiferous tubules, and subsequently transported to the germ cells where it will stimulate meiosis

It has long been known that it is possible to maintain complete spermatogenesis in hypophysectomised animals if they are placed on testosterone therapy immediately after the operation But if the testes are allowed to regress following hypophysectomy, testosterone alone will not restore spermatogenesis, and follicle stimulating hormone is required in addition The present studies suggest that this is because testosterone is only capable of maintaining the secretion of androgen-binding protein by fully developed Sertoli cells

If the male germ cells make inhibin which regulates follicle stimulating hormone secretion, and if this in turn controls the rate of spermatogenesis by influencing the secretion of androgen-binding protein from the Sertoli cells, we have a subtle biochemical interplay between the germinal and somatic elements of the testis But what of the ovary? The anatomical relationship between the cumulus cells and the oocyte is reminiscent of that between the Sertoli cells and the spermatogonia Does the mature oocyte produce the female equivalent of inhibin, and hence regulate gonadotrophin secretion? Do pituitary gonadotrophins act on the granulosa cells to influence secretions which in turn regulate maturation? Little thought has been given to such problems, and yet they might add a new dimension to our understanding of the complex sequence of endocrine events leading up to ovulation

What are the parents?

from W T Toner

NEW ideas are needed to explain muon to pion production ratios as large as 10⁻⁴ in high energy proton interactions Unlike pions, muons and electrons are not strongly interacting and should not be seen in these collisions, except as rare decay products of strongly interacting parents

Anomalously high production of large transverse momentum muons and electrons was reported last summer by several groups in the USA, at CERN and in the USSR, working with protons at energies above 70 GeV Roughly equal amounts of μ^+, μ^-, e^+ and e^- are observed In a recent issue of *Physical Review Letters* (**34**, 103, 1975) Leipuner *et al* claim a similar result for muons with no transverse momentum, in proton-nucleus collisions at only 28 GeV

It is ironic that this latest result comes from a re-analysis of a 1969 experiment which showed the absence of one hundred times larger amounts of 'direct' muon production, then claimed by a Utah group to take place in cosmic ray interactions Those claims found no support and were later withdrawn At that time, there was no compelling reason to make a painstaking analysis of the small residue, which was thought to come from the rare electromagnetic decays of the ρ^0, ω^0 and φ^0 vector mesons, strongly interacting analogues of the photon But models based on this idea require that most of the pions observed at the same energies and angles as the muons originate in the other decays of these same three particles the ρ^0, ω^0 and φ^0 have to be singled out from a hundred and one other ways of generating the ubiquitous pion

Gordon *et al* (*Phys Rev Lett*, **34**, 284, 1975) suggest that this may happen at large transverse momentum, if the rapid increase that they observe in the yield of ρ^0 relative to pions continues beyond 1 GeV/c transverse There is an intuitive appeal to such an idea, since the production of all types of particles at large transverse momentum is unexpectedly high and shows features suggestive

of some electromagnetic analogy How to turn it into a theory is another matter Besides, another mechanism still has to be found to explain Leipuner's data at low transverse momentum, where vector mesons can only account for 10% of the observed muon yield The decay of the η meson (a kind of heavy neutral pion) into two muons and a photon might account for another 15% in this case, but would upset the observed balance between electrons and muons if used to explain the large transverse momentum data

Unfortunately, lack of data on the production of unstable particles prevents us dismissing out of hand the unlikely possibility that known heavier relatives of the ρ^0, ω^0 and φ^0 give rise to the bulk of the muons and electrons They are included in the generic title 'heavy virtual photons' given to the unknown parents

An assortment of ordinary mechanisms would not satisfy the discoverers of direct muons, whose searches had a more glamorous stimulus Theorists have found it necessary to postulate the existence of many new particles in order to account for various features of the weak interaction, more than just the field particles needed to carry the weak force Those ideas have gained more support with the recent discovery of neutral weak currents

According to one class of theories, there should be a whole set of new strongly interacting particles with a new quantum number 'charm' There could even be a fourth degree of freedom, 'colour', to add to isotopic spin, strangeness and charm and give rise to its own family of particles Strong decays of the new particles would be inhibited by selection rules, giving plenty of opportunity for 'direct' muons and electrons to be produced by weak or electromagnetic decays

The J and ψ particles may fit such a scheme, but if their production is as infrequent as is rumoured they cannot

be the source of so many direct muons Are there others, with masses low enough to be produced in 28 GeV proton–uranium collisions?

We can expect many results bearing on these questions in the next few months A new impetus has been given to attempts to measure the production characteristics of the well known unstable particles The complete results of Ting's J-particle experiment should answer some of the mundane questions as well as the more exciting ones Every high energy laboratory is mounting programmes to search for charm and colour Also, many groups are looking again at their 'zoos' of supposed artefacts, conscious that neutral currents, J-particles and the direct muons all gave signs of their presence in earlier experiments, though too faint to create universal enthusiasm for following them up

Polyacrylamide gels

from Paul Calvert

CROSS-LINKED polyacrylamide gels are extensively used in the electrophoretic separation of proteins It is thought that the gel acts as a molecular sieve with a distribution of pore sizes in the 20 Å range so that small molecules pass easily through and large molecules are retarded These gels are prepared by the free radical polymerisation of an aqueous solution of a few per cent acrylamide containing a small amount of cross-linking agent Under these conditions one might reasonably expect to get a homogeneous network Pore sizes calculated on this assumption (see for instance Robard and Chrombach, *Proc natn Acad Sci USA*, **65**, 970, 1970, Hersey and Rees, *Nature phys Sci*, **230**, 92, 1971) are about right for protein dimensions and thus we have a fine example of a simple theory giving good results

Unfortunately for lovers of simple theories, recent scanning electron microscopy of freeze dried gels suggests that the structure is not homogeneous at all Blank and Reimschuessel (*J Materials Sci*, **9**, 1815, 1974) studied similar polyacrylamide gels from the point of view of their suitability as support media for crystal growth Their results show a structure consisting of 2–10 μm walls, surrounding pores of similar dimensions, in a 2 5 weight per cent acrylamide gel As the concentration is increased the walls become thicker This size is suitable for the growth of crystals but huge compared to any protein molecule so that if there is a sieving action it must be within the walls, and will depend on the pores not being interconnected

First we must consider whether the pores are an artefact of the preparation

technique The gels were prepared b ^{60}Co irradiation rather than by catalyst-accelerator system but thi should not be a crucial difference Th usual concentration of cross-linkin agent was used The freeze drying ma have distorted the structure but th kind of large-scale chain breakag needed to create the pores seems un likely Further, a cross-linked polyviny alcohol gel showed only very smal pores after freeze drying

There have been many reports o anomalous behaviour of organic gels In gelatin gels Johnson and Thorntoi (*J Photog Sci*, **16**, 117, 1968) showe that 1 μm particles have considerabl mobility Pines and Prins (*Macro molecules*, **6**, 888, 1973) have demon strated phase separation in agarose anc some polyvinyl alcohol gels but not ir gelatin

Thus there is some evidence for a macroscopic pore structure in severa gel systems which must arise by a liquid–liquid phase separation process analogous to that observed in many polymer solutions below the theta temperature (see Flory's *Principles of Polymer Chemistry*) but with the additional constraint of the cross-linked structure to be accounted for In terms of the electrophoretic separation the presence of the macroscopic pores cannot dc much good and it seem that further study of the relationship between structure and separation could lead to improved gel systems

Changes in species diversity

from Peter D Moore

IF there is one area of ecology in which theoretical speculation has outpaced acquisition of field data it is in the study of succession The time scale involved in most terrestrial successions is of the order of centuries, which leaves the hopeful student with limited options he must either be contented with the study of a series of extant phases which are assumed to be related in a successional series, or he must turn to systems which attain a more rapid equilibrium (such as plankton) for the formulation or confirmation of generalised models Neither course is satisfactory, but life is short

The former alternative has recently been chosen by Nicholson and Monk (*Ecology*, **55**, 1075, 1974) as a means of investigating the vexed problem of diversity changes during succession By obtaining data on the vascular plant composition of 51 seral vegetation types developed on abandoned agricultural land in the Georgia Piedmont, they have produced one of the most extensive sets of information currently avail-

---

ble for the study of diversity changes

The mathematical definition of diversity is in itself a controversial subject Perhaps the most commonly used and widely accepted index of diversity is that derived from the information theory of Shannon and Weaver, which was first introduced into the ecological arena by Margalef (*Gen Syst*, **3**, 36, 958) Although this function has advantages as a general index, it has one major drawback, this being that it compounds species richness (number of species per unit area or in relation to the total number of individuals) and equitability or evenness (the apportionment of individuals among the species present) Both Odum (*Science*, **164**, 62, 1969) and Pielou (*An Introduction to Mathematical Ecology*, Wiley, New York) have pointed out that these two parameters may behave differently during succession and that such differences would be obscured by a simple consideration of the Shannon function

Nicholson and Monk have calculated richness, information content (Shannon diversity) and equitability for their data and in doing so have confirmed Odum's and Pielou's suspicions Richness and equitability (they use Pielou's index, *J*, which divides the Shannon index by the natural logarithm of the number of species see *J theor Biol*, **13**, 131, 966) do behave differently and information content follows an intermediate path Richness increases rapidly during the first 70 yr of abandonment and then continues to rise gradually over the next 130 yr, but within this general trend one can detect periods of stagnation at 10–20 yr (dominance of perennial grass species), 30–80 yr (pine dominance) and at 150–200 yr (climax species, such as *Fagus grandifolia,* attain dominance) Equitability, on the other hand, rises to fairly high levels within 20 yr and subsequently levels off, there is even a tendency to fall in the older stands, possibly due to the increasing degree of dominance

Falling diversity in the later stages of succession has also been observed by Loucks (*Am Zool*, **10**, 17, 1970) in the western Great Lakes region and by Shafi and Yarranton (*Ecology*, **54**, 897, 973) in the boreal forest of northern Ontario These authors interpret this as a product of random catastrophic disturbances which typify temperate and boreal vegetation types For example, within much of the boreal Canadian forests burning is likely to take place at intervals of 200 yr or less Under such conditions, evolutionary pressures might favour 'immature' vegetation types with low equitability in contrast to tropical forest where low perturbation frequency would favour high species richness and equitability

Nicholson and Monk favour the concept of evolutionary influences upon

ecosystem composition as far as richness is concerned, but they consider the equitability component of diversity to be more directly constrained by limited resource availability This would account for the early plateau in the equitability curve since, if resources were limiting, population and biomass growth within any stratum of the vegetation would be curtailed and hence equitability stabilised

From this work it is evident that diversity should not be considered as a single entity when dealing with successions, but should be reduced to its component parts It is sad that such analyses of diversity invariably, and perhaps inevitably, deal with single taxonomic groups of organisms such as birds, vascular plants, or lizards Maybe one should be consoled by the results of Murdoch, Evans and Peterson (*Ecology*, **53**, 819, 1972) who found positive correlation between evenness and diversity of plants and evenness and diversity of Homoptera within old field successions in Michigan Perhaps a consideration of plants alone does have some relevance and relationship to the behaviour of the entire biota during the course of succession, but over-generalisation could still be very misleading

Probing the transcript

from Paul Tolstoshev

THE complementary DNA copy of specific messenger RNA molecules has provided the molecular biologist with a powerful analytical tool Such cDNA molecules are synthesised from mRNA by viral RNA-dependent DNA polymerase, and can be labelled to very high specific radioactivities Molecular hybridisation analysis, using such a cDNA probe, allows the detection of extremely small amounts of a specific mRNA sequence

The analysis, with globin specific cDNA, of RNA transcribed from isolated chromatin by *Escherichia coli* RNA polymerase, has yielded spectacular results The *E coli* enzyme seems to transcribe globin-specific sequences from duck reticulocyte chromatin (Axel *et al*, *Proc natn Acad Sci U S A*, **70**, 2029, 1973), from mouse foetal liver chromatin (Gilmour and Paul, *Proc natn Acad Sci U S A*, **70**, 3440, 1973) and from rabbit bone marrow chromatin (Steggles *et al*, *Proc natn Acad Sci U S A*, **71**, 1219, 1973), but not from duck liver, rabbit liver, or mouse liver chromatin, or from free duck DNA Such results imply that isolated chromatin retains some specificity with respect to the genetic sequences which are available for transcription Furthermore, the

specificity of transcription seems to be mediated by the non-histone protein fraction of the chromatin This conclusion was derived from the chromatin reconstitution experiments of Paul *et al* (*Cold Spring Harb Symp quant Biol*, **38**, 885, 1973), and has recently been confirmed by the experiments of Barrett *et al* (*Proc natn Acad Sci U S A*, **71**, 5057, 1974)

A major problem in assessing the validity of chromatin transcription experiments of this type lies in the presence of endogenous RNA sequences in chromatin preparations Most chromatin preparations contain RNA, and it is perhaps to be expected that globin-specific sequences are contained in the RNA present in chromatin from erythropoietic tissue The cDNA probe cannot, of course, distinguish between endogenous and newly synthesised globin sequences Paul *et al* labelled the transcribed RNA with ^{32}P The hybrid between cDNA and transcribed RNA contained sufficient ^{32}P radioactivity to indicate that a large portion of the globin sequences detected had been newly synthesised But the very small amounts of ^{32}P label in the hybrid make quantitative estimations rather imprecise

Barrett *et al* measured amounts of endogenous globin sequences in RNA from native chicken reticulocyte chromatin, and found relatively high levels (about 0 02% of the total endogenous RNA) Transcription of native reticulocyte chromatin by *E coli* RNA polymerase yielded additional globin-specific sequences in amounts approximately the same as those of the endogenous sequences But when chromatin was separated into DNA, histone and non-histone components, and was reconstituted, either from chicken erythrocyte DNA and histones, and reticulocyte non-histone components, or from all reticulocyte components, no endogenous globin-specific sequences were detected Transcription of the reconstituted chromatins yielded RNA containing 0 007 to 0 025% globin-specific sequences Thus it seems that the preparative procedures used by these authors for DNA, histone, and non-histone protein isolation allowed few or none of the endogenous globin-specific sequences to survive This was confirmed, for the non-histone protein fraction, in a control experiment where erythrocyte DNA and reticulocyte non-histone protein were reconstituted in the absence of any histone When this material was transcribed, no globin-specific sequences were detected

This suggests that there are no globin sequences contaminating the reticulocyte non-histone protein fraction, as well as establishing a histone dependence for correct chromatin

reconstitution Barrett *et al* were able to demonstrate that substitution of the reticulocyte non-histone proteins by chicken liver non-histone proteins prevented the transcription of globin sequences The specificity observed in chromatin reconstitution must therefore be attributed to components of the non-histone protein fraction

The use of such chromatin reconstitution systems as a functional assay for specific non-histone proteins still however remains a formidable task This may be simplified somewhat if purified euchromatin fractions can be successfully reconstituted in the same way (Euchromatin is that fraction of the chromatin thought to be active in transcription *in vivo*) Several groups have isolated fractions of chromatin which seem to have many of the properties expected for euchromatin There has however been, to date, no demonstration that the DNA of such fractions is enriched for the gene sequences which are transcribed *in vivo*, in the cell of the chromatin's origin

An interesting study on the nature of the RNA transcribed *in vitro* from isolated chick myoblast chromatin, by a mammalian RNA polymerase (form B from calf thymus) has recently been reported by Groner *et al* (*Proc natn Acad Sci USA*, **72**, 194, 1975) These authors found that most of the transcribed RNA was of relatively small size (5 to 7S) They demonstrated, by isopycnic gradient centrifugation in CsCl, that a large proportion of this transcribed RNA remained bound to the DNA template The addition of a polyanion, heparin, to their reaction mixture resulted in an increase in the amount and size of the RNA transcript The RNA now sedimented as a broad peak (between 5 to 50S) on sucrose density gradients CsCl density gradient analysis revealed that the larger RNA had apparently been released from the template Pulse-chase experiments established that the small, DNA-bound transcript produced in the heparin was a precursor of the larger material made when heparin was added

A similar effect of heparin on the amount and size of RNA transcribed from chick oviduct chromatin by both mammalian and bacterial polymerase had previously been reported by Cox (*Eur J Biochem*, **39**, 49, 1973) In this case the effect was attributed to the inhibitory effect of heparin on nucleases present in the chromatin Control experiments by Groner *et al* showed that the chromatin used in their study was sufficiently free of ribonuclease activity to eliminate this factor as the major effect of heparin Groner *et al* interpret their results as indicating that the small RNA transcripts made in the absence of heparin are transcribed

from, and remain bound to single-stranded regions of DNA The addition of heparin induces a structural change in the template, resulting in the unwinding of longer stretches of DNA This, in turn, allows production of much longer transcripts, which are presumably displaced from the template by reformation of the DNA duplex As the authors point out, their interpretation is consistent with the model of chromatin structure where the unwinding of DNA to single-stranded regions is required for specific transcription (Crick, *Nature*, **234**, 25, 1971)

Two problems arise in this interpretation of the data First, heparin can cause displacement of chromosomal proteins from DNA (see for example Cox, *ibid*) and Groner *et al* did not determine whether such displacement was caused by the relatively high levels of heparin (2 5 mg ml^{-1}) used in their experiments Second, a search for single-stranded regions of DNA in chromatin by Levy and Simpson (*Nature new biol*, **241**, 139, 1973) revealed only very low levels (no more than 0 01% of the DNA) Nevertheless, it may be of interest to apply the approach of Groner *et al* to the transcription of reconstituted chromatin The use of specific cDNAs may make possible a demonstration that heparin (or other polyanions) can cause release of the transcriptional specificity of chromatin Thus one might perhaps obtain transcription of sequences not normally produced in the cells of the chromatin's origin Whether the action of heparin is mimicking, in some gross way, the action of specific gene regulators in eukaryote cells, remains to be established It is however clear that the *in vitro* reconstitution and transcription of chromatin will continue to be the focus of a great deal of attention in attempts to unravel the intricacies of transcriptional regulation

Pyroxene geotherm supports plumes

from Peter J Smith

In spite of their importance, temperatures in the Earth's interior remain uncertain because they are impossible to measure directly and difficult to estimate indirectly Recently, however, Boyd (*Geochim Cosmochim Acta*, **37**, 2533, 1973) applied pyroxene geothermometry to ultramafic xenoliths in the kimberlite pipes of Lesotho and derived a temperature–depth curve which could well represent real temperatures in the upper mantle He used phase equilibria in the enstatite–diopside and enstatite–garnet systems to obtain the equilibration temperature and pressure of xeno-

liths containing the mineral assembla; enstatite+diopside+garnet The resul ing geotherm suggests that down about 160 km temperature increas with depth in reasonable accord wii the extrapolation of the near-surfac thermal gradient But at a depth (about 170 km the temperature indicate by the pyroxene geotherm begins to ri much more rapidly, increasing t several hundred degrees over a dept of a few tens of kilometres

It is difficult to imagine that th rapid temperature rise represents stead state behaviour But if it is transier (with respect to the lithosphere), wh; causes it? Boyd's own suggestion w; shear heating, which would also explai why the xenoliths from below 170 kr are strongly sheared whereas thos from above are unsheared Unfoi tunately, this hypothesis fails to explai why the intrusions carrying the xenc liths are localised phenomena second possibility would be therm; conductivity variation, but the therm; conductivity would have to decrease b a factor of five, a possible but unlikel change

Parmentier and Turcotte (*Eart, planet Sci Lett*, **24**, 209, 1975) there fore propose that the increase in ge(thermal gradient reflects a relativel localised distortion of the norm; mantle convection pattern caused by mantle plume As they envisage it, col(lithosphere moves over a hot risin; plume The extra heat arriving at th base of the lithosphere would normall; be expected to rise up through th lithosphere by conduction But conduc tion is slow, so that before the hea has penetrated very far, any particula section of lithosphere will have mover away from the plume zone The geo therm in the lithosphere will thu hardly be affected by the plume, excep near the base In other words, the litho spheric and asthenospheric geotherms which are different, remain largely in dependent of each other, and thi accounts for the point of inflection a about 170 km (although the smal amount of conduction into the litho sphere ensures that the two geotherm merge smoothly) By the same token the depth at which the temperature begins to rise rapidly is the lithosphere- asthenosphere boundary

Numerical studies of a model involv ing a cylindrical plume heated from below give results which are consisten with this view That is to say, the total geotherm predicted from the model i in good agreement with Boyd's pyrox ene geotherm as long as the kimberlit(intrusion in the model is located awa) from the plume axis in the directior from which the lithosphere is approach ing Clearly this agreement may b(taken as indirect evidence in favour o| the existence of mantle plumes

Mesozoic apparent polar wander and Atlantic plate tectonics

M. B. Steiner

Institute for Geosciences, The University of Texas at Dallas, PO Box 688, Richardson, Texas 75080

New palaeomagnetic data indicate that the North American apparent polar wander curve followed an approximately latitudinal path for most of the Mesozoic This has important implications concerning the early phases of seafloor spreading in the Atlantic, particularly as Africa seems to have been stationary at that time

THE North American apparent polar wander (APW) curve for the mid Mesozoic is poorly understood and has been the subject of disagreement for some time Data have been particularly inconsistent for the Jurassic Period[1,2] With relatively few reliable Jurassic determinations it has commonly been thought that the APW curve passed from a reasonably well determined point in the Triassic (see Fig a) to a position which is close to the present axial dipole, and then to a well determined Cretaceous position In fact, the Mesozoic APW curve does not pass through the present axial dipole, but follows an approximately latitudinal path present-day coordinates) between the Triassic and Cretaceous pole positions[3,16]

The direction of the path of the pole during the Mesozoic has a direct bearing on our understanding of the early

opening of the Atlantic, especially in light of African palaeomagnetic data Published African palaeopoles for the early Triassic to the early Cretaceous are so similar in their positions as to be indistinguishable from one another at the level of statistical confidence of palaeomagnetic data (Fig 1b) This consistency indicates that Africa was essentially fixed relative to the magnetic pole for most of the Mesozoic The apparent motion of the North American pole, therefore, indicates that the entire motion related to the early opening of the North Atlantic (the separation of Africa from North America) must have been taken up by movement of the North American plate

Before examining the constraints that the newly established North American Mesozoic APW curve places on the opening of the Atlantic, a few points regarding the curve itself need to be examined

North American Triassic poles used by various workers in the reconstruction of the Atlantic always include a group of late Triassic poles displaced more to the north than the rest of the late Triassic poles They have been cited[4] as evidence of rapid polar wander Obviously, the tight grouping of the African poles refutes this hypothesis

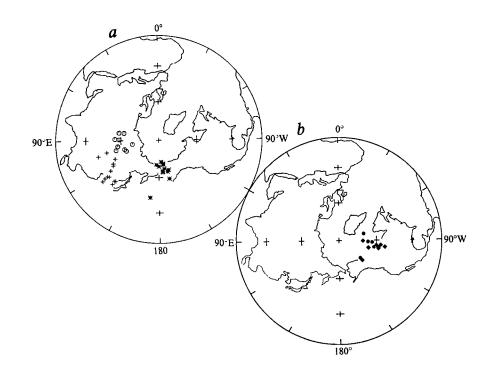
Poles located at these higher latitudes are all derived from


Fig. 1 *a*, Most reliable[16] published poles for the Permian (+), Triassic (O) and Cretaceous (∗), making up the APW curve for North America *b*, Most reliable poles (see refs 9 and 15) for the Triassic (●), Jurassic (◆) and Cretaceous (∗) of Africa
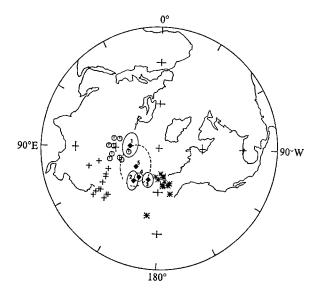

Fig. 2 The North American, Mesozoic APW curve Poles (♦) and ovals of confidence of 1, the Summerville Formation[1], 2 and 3, lower and upper Morrison Formation[16], 4, Mesozoic dykes[6], 5, Topley Intrusions[3], against the background of the Permian (crosses), Triassic (open circles) and Cretaceous (*) poles of Fig 1*a*

rocks of the north-eastern USA and have not been observed in late Triassic rocks of western North America These poles must be viewed with suspicion as they form a streak between the majority of late Triassic poles and the present axial dipole Armstrong and Besancon[5] contend that the Newark Group rocks have been somewhat altered (zeolite facies metamorphism) and are unreliable for K–Ar dating, as most magnetic studies are from rocks associated with the Newark Group it is therefore possible that some of the magnetic directions obtained are unreliable Regardless of the reason, the likelihood that a real streak would occur in the same direction as that expected from the imprinting of secondary magnetisation is so improbable that it should be questioned Furthermore, a number of the studies have a very small sample population

Previous studies on Jurassic rocks have given very inconsistent results The position of the pole determined from the Upper Jurassic Summerville Formation is, however, not much different from that of Triassic time[1] There are no structural uncertainties associated with the data and remagnetisation of a younger unit into an older direction is impossible It is unlikely that the data record an odd direction resulting from secular variation as they encompass a reversal of the field, and therefore probably span enough time to average out extremes of secular variation The Oxfordian Summerville direction seems to indicate that the pole position for North America remained relatively constant from late Triassic to late Jurassic time and that it subsequently moved rather quickly to the Cretaceous position

Magnetic directions obtained from the unit directly overlying the Summerville, the Morrison Formation[16] are in complete accord with the hypothesis that most Mesozoic APW relative to North America occurred over a relatively short time during the late Jurassic Two different directions have been obtained from sediments in the lower and upper parts of the Morrison formation (Kimmeridgian–Tithonian respectively The directions lies in sequential position on the APW curve and suggest that about 10° of apparent motion of the pole occurred during Morrison time These directions also imply that about twice that amount of apparent motion occurred between the Summerville and the lowest sampled portion of the Morrison (Fig 2)

(More than 35 m of unsampled sediments, and a probab unconformity, exist between the lowest sampled beds the Morrison and the Summerville) The Morriso and Summerville data indicate that the majority of th movement occurred in post-Summerville time, that is, lat Oxfordian(?), Kimmeridgian and Tithonian The olde dated Cretaceous rocks studied palaeomagnetically sho pole positions already located in the position shown by lat Cretaceous rocks

The Morrison data also confirm that the APW path w approximately latitudinal relative to the present axial po and did not include the present dipole The averag direction of the Topley Intrusions[3] agrees with this hyp thesis, although the confidence limits on the data are qui large A pole in the same area has also been obtained t DeBoer[6] from some dykes of unknown age cutting Upp Triassic rocks

This APW path requires that the pattern of separation Africa and North America be somewhat different from th proposed previously Pitman and Talwani[7] have compute finite difference poles to describe the rotations needed t open the central Atlantic Rotation of the North America plate about the oldest (180–155 Myr) pole of opening w produce very little apparent motion of the magnetic pol relative to North America as the magnetic and rotation poles are very close together That supports my finding that the magnetic pole was approximately static relative t North America from the late Triassic through the m Jurassic and into the beginning of late Jurassic time

Rotation about Pitman and Talwani's[7] next pole c opening (155–81 Myr ago), however, does not move averag late Triassic poles[8,9] through the positions represented b the Morrison poles Nor does this rotation move the pole t the position of the North American Cretaceous poles Th positions of the lower Morrison, Topley, and perhaps th Mesozoic dyke poles suggest a two stage rotation during th Jurassic one additional rotation to that suggested by Pitma and Talwani[7] for the time between rifting and 81 Myr BP The pole to this rotation must lie on a great circle tha passes midway between the late Triassic and lower Morriso poles The rotational pole must lie at some point betwee the small circle connecting these magnetic poles and a poin on the North American continent, in order to produce bot the APW observed and the actual motion of North Americ relative to Africa This indicates that North America mus have undergone a clockwise rotation relative to Afric before it moved away causing the opening of the Atlantic The rotation following the clockwise rotation was probabl about Pitman and Talwani's[7] 180–155 Myr pole of opening as that moves the pole approximately from the lowe Morrison position through the upper Morrison position an into the Cretaceous position

The path of polar motion defined by the sequentia Summerville and Morrison poles corresponds to a change ir direction of APW during the Jurassic (Fig 2) The timing of this change of direction is interesting The Morrison polarity sequence can be correlated[16] with the oldest anomalies of an M sequence anomaly pattern[17] Thus, the lower Morrison pole represents the pole of the oldest of the Mesozoic anomalies This means that the change in direction of the pole path occurred just before the formation of the lineated anomalies The change coincides with the changes from rough to smooth and from magnetically quiet to lineated-anomaly sea floor, and may, therefore, indicate a causal relationship

The stationary position of Africa throughout most of the Mesozoic may have been conducive to asymmetrical spreading in the Atlantic Indeed, the quiet zone boundaries on either side of the Atlantic are not symmetrical with respect to the continental margins[10,11] At least two mechanisms could produce these different widths of sea floor on either side of the Mid-Atlantic Ridge[12] either an eastward jump

of the ridge crest or a migrating ridge crest, would produce asymmetry. The stationary position of the African plate requires that the spreading crest be in motion at the time of formation of the marginal quiet zone and the late Jurassic–early Cretaceous anomalies. These data therefore favour the migrating ridge system as the cause of the asymmetry, suggesting that both the North American plate and the ridge crest may have been migrating away from Africa, with the plate moving much faster. Later, however, during the time between the end of the quiet zone and anomaly 32, the African pole still shows no motion although the zones of the sea floor representing this time are quite similar in width on both sides of the Atlantic. This suggests that the ridge crest may by then have started to migrate rapidly enough to produce symmetrical spreading during that time.

If the Morrison and Summerville poles are truly representative of sequential positions of the Jurassic pole along an APW path created by seafloor spreading, very high rates of seafloor motion are implied. An approximate idea of the rates involved can be obtained from equations used by Deutch[13]. Although Pitman and Talwani's[7] rotational pole does not rotate the mean late Triassic pole into the position of the mean Cretaceous pole, an approximate seafloor spreading rate can be obtained by computing the rate of plate movement about this rotational pole that would bring the Triassic pole closest to the Cretaceous pole. The amount of time allowable for the rotation is considered to be approximately 20 Myr (early Oxfordian to early Cretaceous —for numerical ages see ref. 14), based on the position of the Summerville pole. I have computed the rates at 45° away from the rotation pole, that is, within the area of the sea floor between Africa and North America. A rate of 16–19 cm yr⁻¹ is necessary at this distance to produce the total opening for that time[7]. (The uncertainty stems from the choice of the various[1,8,9] Triassic poles which can be used.) The rate for just the motion between early Morrison and early Cretaceous time (around this same rotational pole), allowing 15 Myr (from the base of the Kimmeridgian to the base of the Cretaceous), at 45° from the pole, would be 12.5 cm yr⁻¹. These are quoted as whole rates, as the ridge system was probably also in motion. They are rates for the time of formation of some portion of the quiet zone and anomalies M22 to M25.

Even if the rates are considered in terms of half rates, both computations give a surprisingly high rate of seafloor spreading. The rates are far in excess of any that have been proposed for the Atlantic, and rank among the highest rates ever proposed for any spreading ridge. Such high rates may have occurred as some consequence of the initial spreading process, or they may indicate events that caused a drastic slow-down in Atlantic spreading subsequent to opening.

Nuclear envelope permeability

Philip L. Paine, Leonard C. Moore & Samuel B. Horowitz

Cell Physiology Laboratory, Michigan Cancer Foundation, Detroit, Michigan 48201

The permeability of the amphibian oocyte nuclear envelope in situ has been determined for three tritiated dextrans. The envelope is a sieve, restricting molecular movement between the cytoplasm and nucleus. The patent radius of its pores is about 45 Å.

MANY substances are known to be in continuous exchange across the nuclear envelope. These include ions and metabolites[1-3]; histone and non-histone chromosomal proteins[4-6]; ribosomal and messenger ribonucleoproteins[7-9]; hormones, either free or bound to protein receptors[10]; viral proteins and nucleic acids[11-13]; and less characterised protein and RNA species[14-15]. Yet, because quantitative flux data are almost non-existent, we know little about the factors that govern the passage of these substances through the nuclear envelope, and we cannot assess the envelope's role in controlling nucleocytoplasmic exchange.

The most direct method of obtaining rate data on nuclear envelope permeation is to microinject a substance into the cytoplasm and follow its passage into the nucleus with quantitative optical or electron microscopic techniques. Solutes used for such studies have been chosen primarily for technical rather than heuristic reasons. With the advent of ultra-low temperature autoradiography (ULTA)[16], which can quantitatively locate any tracer substance regardless of its diffusibility, a systematic approach to the problem of envelope permeation becomes possible, since any radioactively labelled substance can serve as a probe.

Size has been the most studied of the permeant properties which influence nuclear envelope passage. Colloidal gold particles greater than 125–145 Å in diameter do not penetrate the nuclear envelope of Amoeba proteus[17]. Ferritin, with a molecular diameter of 95 Å, does not enter the nuclei of amphibian and cockroach oocytes[18,19]; below this limit, permeation is inversely related to tracer size. Passage of proteins (molecular weight 12,000–67,000; radii ≈ 15–35 Å) is slowed by the nuclear envelopes of the cockroach oocyte[19] and chironomid salivary gland cell (P.L.P., unpublished), the degree of slowing increasing with increased molecular size. Slowing is not observed when tracers are 4,200 dalton or less.

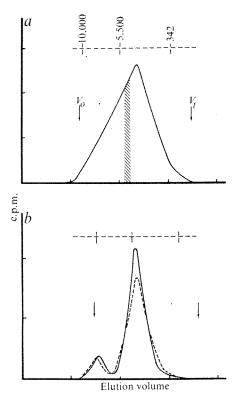
While these observations reveal some nuclear envelope sieving properties, a more quantitative understanding requires nucleocytoplasmic flux and equilibrium data on a size-graded series of molecules with otherwise similar properties. We have obtained such data for size-characterised fractions of dextran, a polymer of D-glucopyranose units linked by α-1:6, α-1:4, and α-1:3 glucosidic bonds. Dextrans in aqueous solution are considerably hydrated and behave as spheres[20]. The hydrodynamic radii of our tracer fractions were 12.0, 23.3 and 35.5 Å (Table 1). Solutions of purified ³H-dextran were microinjected into the cytoplasm of mature oocytes of Rana pipiens. Solute diffusion was permitted until the cells were quenched at −190 °C. The oocytes were sectioned at −50 °C, and the local intracellular concentrations of tracer determined using ultra-low temperature autoradiography. Figures 1 and 2a and b summarise the preparation and microinjection of the ³H-dextran fractions, the autoradiographic procedures, and the tests for intracellular ³H-dextran degradation.


Fig. 1 *a*, Gel chromatographic isolation of 12.0 Å ³H-dextran tracer. Commercially obtained ³H-dextran (specific activity 0.4 mCi mg⁻¹, lot No. 622-215, New England Nuclear, Boston) in water was fractionated on Sephadex G-50 to remove > 10,000 dalton dextrans (not shown). A portion of the remaining material was rechromatographed on Sephadex G-50, yielding the distribution shown. A subfraction (shaded), with hydrodynamic radius 12.0 Å, was isolated for injection and was concentrated by lyophilisation to 650 µCi ml⁻¹. *b*, The size distribution of the injectate was confirmed on Sephadex G-50 at the time of microinjection (————); no breakdown and only negligible polymerisation (a time-dependent process observed with 12.0 Å dextrans) was detected. Intracellular stability was established by homogenising four cells 40 h after microinjection and chromatographing the 12,000*g* supernatant (. . . . .). ³H-dextran injectates (23.3 and 35.5 Å) were prepared similarly using Sephadex G-50 and G-75 columns. All columns were equilibrated with water and eluted to stable total volumes (*V*ₜ) before use. Void volumes (*V*₀) were determined with Blue Dextran 2,000, and molecular size calibrations were carried out using sucrose (342), inulin (5,500) and dextrans (10,000, 20,000, 40,000 and 70,000) as standards.

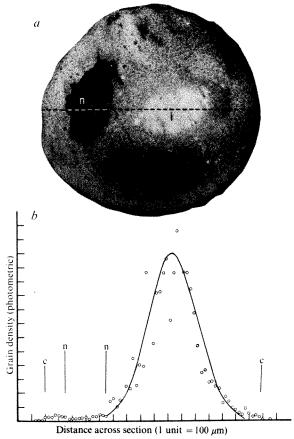
Cytoplasmic diffusion


Immediately after microinjection, the ³H-dextran is found at the injection site, observed in autoradiographs as an intense concentration of silver grains. The tracer then diffuses radially from the injection site, and grain density transects show time-dependent diffusion profiles. Cytoplasmic diffusion coefficients, *D*c, are estimated by comparing the cytoplasmic profile at a known diffusion time (*t*d) with theoretical diffusion profiles (Fig. 2c). The analysis has been outlined previously for sucrose²⁶ and inulin²⁷ in the oocyte, for which *D*c are 2 × 10⁻⁶ and 3 × 10⁻⁷ cm² s⁻¹, respectively. Our estimates for *D*c of 12.0, 23.3, and 35.5 Å ³H-dextrans are 3.5 × 10⁻⁷, 2.5 × 10⁻⁷ and 1.5 × 10⁻⁷ cm² s⁻¹, respectively. Over the 70-fold molecular weight range of substances studied in the oocyte, *D*c are in the range 0.1*D*w – 0.4*D*w (*D*w is the solute diffusion coefficient in pure water); this agrees with estimates of *D*c/*D*w reported for a variety of tracers in other cells²⁶,²⁸.

Nuclear envelope permeation

Grain density profiles of oocytes in which the diffusion front has reached the nucleus reveal the nuclear envelope's influence on solute movement. Figure 3a–d, showing profiles for 12.0 Å ³H-dextran at *t*d = 3, 5 and 16 min, and 16 h, are transects made close to the injection site and through the nucleus.

At diffusion equilibrium, 12.0 Å ³H-dextran is uniformly distributed within both the nucleus and the cytoplasm (Fig. 3*d*), but it is more concentrated in the nucleus (see also Fig. 4*a*). A higher concentration in the nucleus than in the cytoplasm has been observed with every solute we have studied in the oocyte. This phenomenon has also been found in other cells and has been attributed to solute exclusion by the cytoplasm, a process widely associated with macromolecular gels²⁷.

At shorter diffusion times, 12.0 Å ³H-dextran gradients are discontinuous, decreasing sharply at the level of the nuclear envelope (Fig. 3a–b). Since this is obviously not caused by low nuclear solubility, the nuclear envelope must be a substantially greater transport barrier than is a similar thickness of cytoplasm. Intranuclear 12.0 Å gradients mirror those in the adjacent cytoplasm. The envelope, although a sufficient barrier to cause gradient discontinuities, is insufficient to isolate nuclear from cytoplasmic gradients. This suggests that the time required for 12.0 Å ³H-dextran to cross the nuclear envelope is less than that required to diffuse the radial distance of the nucleus.

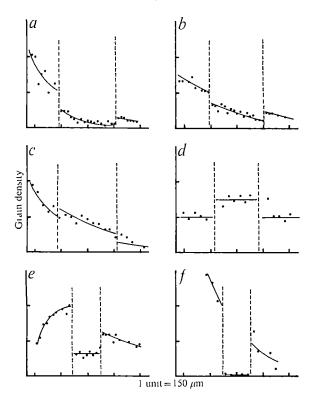
Fig. 2 Microinjection was directed into the vegetal cytoplasm to eliminate the possibility of nuclear damage. Injectate concentrations were 1.6, 1.0 and 0.7 mg ml⁻¹ for 12.0, 23.3 and 35.5 Å ³H-dextrans, respectively; and volumes were 5 × 10⁻⁵ ml, or about 2% that of the cell. After a period of time (*t*d), the oocyte was rapidly embedded in OCT and quenched to – 190 °C in liquid nitrogen. Sectioning and autoradiographic exposure were carried out at – 50 °C and – 96 °C, respectively. This procedure prevents solute redistribution from the time of freezing until completion of the autoradiograph¹⁶. *a*, Autoradiograph, in darkfield illumination, of a section through both the injection site (i) and nucleus (n) of an oocyte injected with 12.0 Å ³H-dextran (*t*d = 8 min). Grain counting was carried out visually, in phase contrast at × 2,000, or photometrically, with a Leitz MPV-1 microscope photometer system employing Ploem incident-light illumination²⁴. Grain density values throughout have been corrected for the difference in nuclear and cytoplasmic water content²⁵ and are proportional to ³H-dextran concentrations on a water basis. *b*, Grain density profile taken along the axis shown as a dotted line in (*a*). The vertical bars, c and n, mark the cell and nuclear boundaries. The solid line is the theoretical diffusion gradient for *D*c = 3.5 × 10⁻⁷ cm² s⁻¹, assuming that the injection volume is small enough to constitute an instantaneous point source, and that solute reflection from the cell boundaries is negligible.


Fig 3 Grain density profiles through the nucleus (indicated by vertical dashed lines) and adjacent cytoplasm of ^{3}H-dextran injected oocytes a–d, 12 0 Å, $t_d = 3$ min, 5 min, 16 min, and 16 h, respectively, e, 23 3 Å, $t_d = 10$ min, f, 35 5 Å, $t_d = 42$ min

Figure 3e and f are grain density profiles for 23 3 and 35 5 Å ^{3}H-dextrans Both profiles decrease more sharply at the nuclear envelope than do the 12 0 Å ^{3}H-dextran profiles at comparable times, but, unlike the latter, the 23 3 and 35 5 Å profiles show uniform transnuclear concentrations, in spite of marked gradients in the adjacent cytoplasm These profiles demonstrate that the nuclear envelope is less permeable to larger dextrans than to smaller, and that envelope permeability can play a major role in limiting the rate of nuclear entry

Quantitative expression of the envelope's influence on solute transport is complicated by the fact that cytoplasmic and nucleoplasmic diffusions are not instantaneous, hence, each point on the nuclear envelope experiences different and changing concentrations of the permeating solute To deal with this problem, we compared solute concentrations in adjacent nuclear and cytoplasmic positions by determining the grain density, G, at Q positions $(i, j, k\quad)$ inside, but close to the edge of, the nucleus $(G_n^i, G_n^j\quad)$ and in the adjacent cytoplasm $(G_c^i, G_c^j\quad)$ The mean of the ratios of adjacent nuclear and cytoplasmic sites is the nuclear cytoplasmic grain density, given by

$$X_{n/c} = (G_n^i/G_c^i + G_n^j/G_c^j + \quad)/Q \tag{1}$$

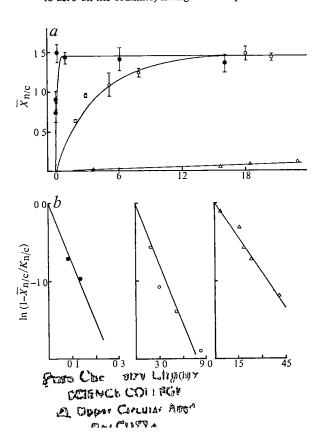
$X_{n/c}$, expressed as a function of t_d, is a measure of the time course of nuclear envelope permeation Figure 4a shows this for the three ^{3}H-dextrans investigated The nuclear entry rates are markedly different, equilibrium is reached for 12 0 and 23 3 Å ^{3}H-dextrans in about 0 5 and 15 h, respectively, with an equilibrium distribution ratio, $K_{n/c}$, of 1 45 The 35 5 Å ^{3}H-dextran enters much more slowly, $X_{n/c}$ at 23 h being 0 1, and does not achieve equilibrium during the experiments

If cytoplasmic and nuclear diffusion are rapid as compared with envelope permeation, and if permeant dwell time within the envelope is short relative to t_d (as the profiles of Fig 3 suggest), the kinetics of diffusional nuclear filling can be described by

$$1 - (X_{n/c}/K_{n/c}) = \exp(-k_n t_d) \tag{2}$$

in which the rate constant, k_n, is given by

$$k_n = P_n A/V_n \tag{3}$$

where P_n is the nuclear envelope permeability coefficient, A is the envelope area available for permeation, and V_n is the nuclear volume If cytoplasmic or nucleoplasmic diffusion significantly affected nuclear entry, a higher order equation would be necessary to describe the kinetics The greater such intracompartmental diffusion influences, the more poorly equation (2) will describe nucleocytoplasmic tracer movement[28]


The nuclear entry kinetics of all three ^{3}H-dextrans are described by first order exponential equations of the form of equation (2), (Fig 4b–d) We conclude that $X_{n/c}$ corrects for spatial differences in tracer concentration arising from the transcellular diffusion, and that nuclear entry is primarily restricted by the nuclear envelope The experimentally determined rate constants, k_n, are given in Table 1 Although the 35 5 Å ^{3}H-dextran differs in molecular radius from the 12 0 Å by a factor of only 2 9 its rate of permeation differs by a factor of more than 2,500 This sieving effect seems to arise from the specialised porous structure of the nuclear envelope

Functional pore size

If we view the nuclear envelope as a uniformly permeable barrier, A in equation (3) is the total nuclear surface area and, assuming a spherical nucleus of radius r_n, we have

$$P_n = k_n r_n/3 \tag{4}$$

Fig. 4 a, Time course of nuclear envelope permeation, expressed as the average nuclear cytoplasmic grain density, $\bar{X}_{n/c}$ (see text), as a function of diffusion time after microinjection, t_d, for 12 0 (●), 23 3 (○), and 35 5 Å (△) ^{3}H-dextrans Vertical bars indicate s e mean b–d, First order exponential entry kinetics illustrated by plots of ln $(1 - \bar{X}_{n/c}/K_{n/c})$ as a function of t_d, for 12 0, 23 3 and 35 5 Å ^{3}H-dextrans, respectively $K_{n/c}$ for 35 5 Å ^{3}H-dextran is assumed to be 1 45, the same value observed for 12 0 and 23 3 Å ^{3}H-dextrans Note the different time scales on the abscissae The rate constants, k_n of Table 1 are given by the slopes of the linear least squares regression lines (constrained to zero on the ordinate) fitting the data points

Table 1 ^{3}H-dextran tracer data			
Radius (Å)	k_n‡ (s⁻¹)	P_n (cm s⁻¹)	A_p (cm²)
12 0*	$(2\,13 \pm 2\,94) \times 10^{-3}$	$1\,60 \times 10^{-5}$	$2\,21 \times 10^{-13}$
23 3†	$(7\,16 \pm 2\,61) \times 10^{-5}$	$5\,37 \times 10^{-7}$	$1\,04 \times 10^{-14}$

*Determined from position of elution peak from Sephadex G-50 ($K_{av} = 0\,40$) and the calculations of Laurent and Killander[21]

†Weight average molecular weights (M_w) were determined by Sephadex chromatography with standard dextrans, and the corresponding molecular radii taken from the measurements of Granath and Kvist[22]

‡The k_n is the slope of the least squares regression line calculated to fit the data points and constrained to zero on the ordinate (Fig 4b–d) The ± value given is the 95% confidence interval for the slope[23], the confidence interval for 12 0 Å dextran is misleadingly large since only two pre-equilibration data points were obtained, and the method of calculation does not admit use of the relevant early equilibrium points shown in Fig 4a

P_n and A_p calculated as explained in text ($r_n = 225$ μm)

from which we can calculate the envelope permeability coefficient, P_n, for each ^{3}H-dextran (Table 1) P_n is probably not, however, a functionally significant measure of nuclear membrane properties There is reason to believe, from both envelope ultrastructure and electron microscopic studies of colloidal gold and in vivo ribonucleoproteins, that passage of macromolecules through the envelope is restricted to a cylindrical central channel of each nuclear pore complex[3] If this is true for our ^{3}H-dextran tracers, we can calculate the total effective envelope pore area available for permeation, A_p^{total}, substituting D_p/d for P_n in equation (3) where D_p is the ^{3}H-dextran diffusion coefficient within the pores, and d is the pore complex length Then

$$A_p^{total} = k_n V_n d / D_p \qquad (5)$$

and the mean effective area available for diffusion through each pore, A_p, is given by

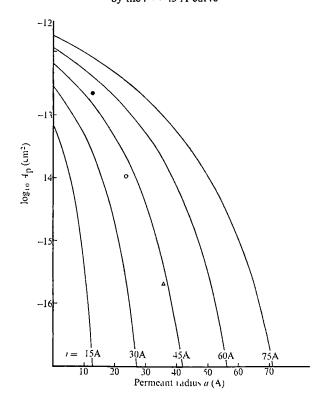
$$A_p = A_p^{total}/N \qquad (6)$$

where N is the number of patent pores per nucleus The best available estimate of d is 1,500 Å (refs 29–33), and of N, $1\,97 \times 10^7$ (refs 34 and 35) D_p is assumed to be equal to D_c, and A_p for each ^{3}H-dextran is shown in Table 1

For a membrane with pores of radius r, A_p is equal to the total patent area of a pore, πr^2, reduced by two solute–pore interaction factors, each a function of a/r (refs 36 and 37) The first expresses the steric hindrance to pore entry[38], the second is a 'wall correction factor', K_1, describing the frictional resistance to diffusion within a cylindrical pore relative to that in free solution Thus, A_p decreases with increasing tracer radius a

$$A_p = \pi r^2 [1 - (a/r)]^2 (1/K_1) = \pi (r - a)^2/K_1 \qquad (7)$$

Haberman and Sayre[39] provided a theoretical solution for K_1 which fits well the available experimental results over a large range of a/r (ref 40) We have applied computer techniques to the solution method of Haberman and Sayre to calculate the values of K_1 over the range $0 < a/r < 1\,0$ at intervals of $0\,02$ units (P L P, and P Scherr, unpublished) The calculated K_1 values were used to construct the curves in Fig 5, which illustrates the dependence of A_p on a and r The experimentally determined A_p for 12 0, 23 3, and 35 5 Å dextrans correspond to r values, determined from equation (7), of 49 0, 40 7, and 43 3 Å, respectively The mean of these determinations is 44 3 Å, in Fig 5, the three plotted A_p values are best fit by the $r = 45$ Å curve We conclude that the ^{3}H-dextran nuclear entry kinetics can be explained quantitatively as restricted diffusion through nuclear pores with patent radii of about 45 Å

There is some uncertainty over the factors (V_n, d, D_p, and N) which enter the calculations of A_p We have determined the ranges


of A_p, and the corresponding ranges of r, resulting from reasonable ranges of each factor around the values used above For the 35 5 Å ^{3}H-dextran data, an error of ± 10% in the value of the nuclear radius (r_n) would correspond to a range of less than ±1 Å about the determined r Possible ranges for the value of D_p (0 1–0 4 × D_w), d (750–2,000 Å), (refs 30, 35 and 41), an N (1 02–3 12 × 10⁷), (refs 34, 35 and 42) each correspond ranges less than ± 3 Å about the 35 5 Å ^{3}H-dextran determine value of r Similarly, variation of ±10% in the value used fo 35 5 Å ^{3}H-dextran radius (a), results in a ± 4 Å change in r Thu unless all values chosen err in the same direction, determinatic of r from A_p and a by equation (7) is not greatly affected b possible errors in the values of the factors used

Permeability of the mature oocyte nuclear envelope

Results of earlier studies of the permeability of the matur amphibian oocyte nuclear envelope are consistent with th nuclear entry kinetics expected for passage through an envelop with pores of radius 45 Å, as reported here The solutes used, order of increasing size, include sodium[1], glycerol[43], cy teamine[44], sucrose[26], inulin[27], histones[18], polyvinylpyrrolidon coated colloidal gold[45,46], bovine serum albumin (BSA), (ref 18 and ferritin[18] Solutes the size of sucrose ($a = 4\,4$ Å, ref 36) o smaller reportedly enter the oocyte nucleus rapidly Intermedia size solutes—histones, colloidal gold, and BSA—enter mor slowly, while ferritin ($a = 47$ Å) does not enter at all

In principle, diffusion of all solutes is influenced by the nuclea envelope Our ability to detect this influence, however, is limited to cases in which half-times for nucleocytoplasm equilibrium, $t_{1/2}$, are at least several minutes—the time re quired to microinject and freeze the oocyte In practice th condition is met only with larger solutes, as illustrated in Fig 6 where $t_{1/2}$ for the mature oocyte nucleus at 15 °C is plotted as function of permeant radius, a As examples, in the oocyte wil

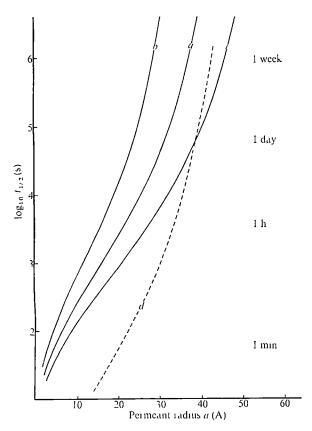
Fig. 5 Mean effective cross-sectional area for diffusion through each pore (A_p), as defined by equation (7), plotted as a function of tracer radius, a, for several pore radii, r Values of A_p determined experimentally (equations (5) and (6)) for 12 0 (●), 23 3 (○) and 35 5Å (△) ^{3}H-dextrans are indicated by points, and are best fit by the $r = 45$ Å curve


Fig 6 Half-times for nucleocytoplasmic equilibration of permeants with radius a by restricted diffusion through nuclear envelope pores (at 15 °C) a, Mature amphibian oocyte nucleus, with $r = 45$ Å, b and c, oocyte nucleus, if $r = 35$ and 55 Å, respectively, d, cell with 5 μm nuclear radius and $r = 45$ Å

$= 45$ Å a solute with radius 5 Å exchanges with a $t_{1/2}$ of bout 1 min, and the reported[27] inability to detect an envelope influence on oocyte nuclear entry of inulin ($a = 14\,8$ Å, ref 22, $_{1/2} \approx 10$ min) probably results from the use of too large a value or t_d as the earliest time studied

Since $t_{1/2}$ is proportional to nuclear radius (equations (2) and 3)), the entry half-time for a given permeant would be shorter n smaller cells than in the oocyte Fig 6d is a plot of $t_{1/2}$ against t for a 5μm radius nucleus assumed to share all of the properties other than size) of the oocyte nucleus The plot provides a notion of the time scale of nuclear permeation to be expected in he typically smaller cells of most multicellular organism tissues

Nuclear envelope permeability in other eukaryotes

Generalisations based on the present analysis will be valid only to the extent that the amphibian oocyte nuclear envelope is similar to other eukaryote envelopes Nuclear envelope ultrastructure is extraordinarily conservative, envelope similarity has been demonstrated in cells as phylogenetically distant as amphibian oocytes, amoebae, dipteran salivary gland cells, HeLa cells, normal and cancerous liver cells, and onion root tip cells[3,33,47] Several studies using insect oocytes[19,48], amoebae[49], HeLa cells[6], and salivary gland cells (P L P , unpublished), have yielded semi-quantitative nucleocytoplasmic exchange kinetics consistent with a patent pore radius about that determined in the present quantitative experiment These studies included microinjection of flourescein-labelled proteins, electron microscopic localisation of colloidal gold and ferritin, and autoradiographic localisation of endogeneous proteins Thus, both morphological and tracer studies suggest that the mature amphibian oocyte nuclear envelope is representative of eukaryote envelopes in general

The eukaryotic envelope consists of two 70–80 Å unit membranes, separated by a perinuclear space, and fused at intervals to form pore complexes 400–1,000 Å in diameter An element of each complex is a cylindrical proteinaceous structure extending through the complex into both cytoplasm and nucleoplasm[3] These structures are annular in cross section and are widely considered to be tubes with patent central channels of 50–300 Å, most frequently 100–150 Å (refs 32, 34 and 50) Three lines of evidence support the view that these pore-complex channels are the sites of nucleocytoplasmic macromolecular exchange (1) Colloidal gold particles, passing from cytoplasm to nucleus, seem to be limited, by the annular material, to these central channels[17] , (2) ribonucleoprotein-containing particles in nucleocytoplasmic transit seem to narrow down to 100–200 Å in diameter as they squeeze through the central region of the pore complex[49], and (3) as shown here, a model based on restricted diffusion through tubular pores could account for a 2,500-fold difference in the rate of nuclear envelope permeation among solutes which differ only in molecular size If this model of the nuclear envelope as a diffusion-restricting barrier with patent pore radii of about 45 Å can be extended to include other cells, significant implications follow

Diffusable cellular metabolites and proteins with radii smaller than 45 Å move between nucleus and cytoplasm through pores at rates influenced by solute size (that is, a/r) As illustrated by plots of $t_{1/2}$ against a (Fig 6), relatively small changes in the effective radius of the solute profoundly affect rates of envelope permeation, thus providing the cell with a method of controlling the nucleocytoplasmic movement of solutes In this regard, there is evidence to suggest that the ability of cytoplasmic oestrogen receptor protein to enter the nucleus is controlled by enzymatic modification of the receptor's dimensions[10,51]

Most cellular proteins are of a size[52] that makes their movement susceptible to influence by small changes in pore radius Hence, it is possible that the envelope controls nucleocytoplasmic movement by variation of the patent pore radius Indeed, there is evidence that the patent pore radius is different in different cell types and varies within a single cell type as a function of the cell cycle and nutritional state[3] Comparison of Fig 6a–c shows that a $\pm\,10$ Å change in the oocyte pore radius would effect a two- to threefold change in the $t_{1/2}$ of ions and metabolites ($a = 5$ Å), a tenfold change in the $t_{1/2}$ of small proteins ($a = 18$ Å), and more than a 1,000-fold change in the $t_{1/2}$ of large proteins ($a > 31$ Å)

Among the most important materials transported between nucleus and cytoplasm are ribonucleoprotein particles, which are believed to be the transport forms of mRNA and rRNA These have radii greater than 45 Å and are too large to diffuse through the nuclear pores Conformational changes in the particles and/or the pore complexes would be necessary for their transport Such changes have been inferred from electron micrographs[53–56] and suggest the possibility of nuclear pore complex control of protein synthesis

Finally, as solute size approaches the dimensions of the pore, solute–pore wall interactions become increasingly important Specific site interactions, for example H-bonding and charge-charge interactions, would also then influence solute movements The demonstration that *Rana pipiens* annular material proteins have a net positive charge[45] supports the idea that factors other than size influence nuclear envelope permeability

Sequence of the O_R operator of phage λ

Vincenzo Pirrotta

Department of Microbiology, Biozentrum der Universitat Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland

A sequence of 79 nucleotides from the λ O_R operator is obtained by primed transcription of repressor protected DNA fragments The sequence contains the primary repressor binding site plus partial duplications which can be interpreted as secondary repressor binding sites

THE λ repressor is a protein which controls the functioning of early phage genes by binding to two sites in the λ DNA known as the operators[1] Repressor bound to the operator prevents the RNA polymerase from transcribing the two early operons of λ[2] This simple model is complicated by the fact that, unlike the *lac* operator[3], the λ operator is a large and complex structure containing several repressor binding sites[4] At low concentrations, repressor binds preferentially to a primary site which is about 30 base pairs long and is located at the operator end nearest the genes of the operon At higher repressor concentrations, the remaining sites are progressively occupied, covering a total region approximately 110 base pairs in length The two operators of λ, O_L and O_R, have a similar structure but differ somewhat in their affinity for repressor O_L is reported to bind repressor about five times more tightly than O_R (ref 4)

Maniatis *et al*[5] have reported a sequence for the primary repressor binding site in the O_L operator They made use of the fact that O_L (as well as O_R) contains a site cleaved by the *Hind* II restriction endonuclease[6] Treatment of O_L or O_R with this enzyme cuts off from the operator a fragment of 30 base pairs containing the primary repressor binding site (Fig 1) Maniatis *et al* were able to sequence this fragment utilising the cleavage product containing the remainder of the operator as a primer for repair synthesis by DNA polymerase

Working with O_R, I have obtained a sequence of 80 nucleotides using RNA polymerase to transcribe operator fragments obtained by protecting the operator with repressor against nuclease digestion This paper is a preliminary report and discussion of the possible implications of this sequence which starts in the middle of O_R and extends to the end of the operator including the primary repressor binding site

O_R operator fragments were prepared in microgram amounts[7]

by digesting with pancreatic DNase the complex formed excess λ repressor and several milligrams of sonicated DN extracted from λd*bio* M30-7, a phage containing only t right-hand operator The product, collected on nitrocellulo filters, extracted and purified by gel electrophoresis, w primarily a fragment about 110 base pairs in length as dete mined by gel electrophoresis I used these fragments as template for transcription by *Escherichia coli* RNA polymeras Whether native or denatured, both strands were transcrib yielding a heterogeneous product ranging from very shc chains to chains nearly as long as the template This materi digested with RNase T_1, gave fingerprints containing a b wildering number of spots Analysis of these nucleotid revealed, however, that many of them were related and result from the heterogeneous starts and stops made by the RN polymerase Making use of nearest neighbour information and analysis with pancreatic RNase and RNase U_2, I w able to obtain the sequence of the T_1 oligonucleotides but tl heterogeneity of the product prevented further progress establishing a total sequence

Specific initiation

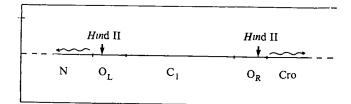
It has been shown by several workers[8-10] that at sufficient low nucleotide triphosphate concentrations, the RNA pol merase can no longer initiate transcription but can still elonga


Fig 1 Schematic map of the control region of phage λ The primary repressor binding sites in O_L and O_R are located between the R *Hind* II cleavage sites (↓) and the initiation of transcription (→)
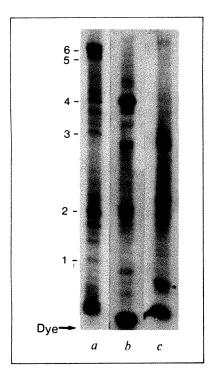

Fig. 2 Gel electrophoresis of ApApA primed transcription of O_R fragments. O_R operator fragments were prepared as previously described[7] from λd*bio* M30-7 DNA. Heat denatured fragments (about 0.2 μg) were transcribed with 5 μg RNA polymerase holoenzyme in a 50–100 μl reaction volume containing 0.05 M KCl, 0.05 M Tris pH 8.0, 0.01 M $MgCl_2$, 0.5 mg ml^{-1} bovine serum albumin, 0.1 mM dithioerythritol, 0.5 mM ApApA and 1–5 μM NTPs of which one or more were labelled with α-^{32}P at 100 μCi Mmol^{-1}. Some unprimed transcription is already detectable when the NTP concentration is as high as 5 μM. The reaction was stopped after 2 h at 37 °C by the addition of 10 μl 0.5 M EDTA and 100 μl M NH$_4$OAc and precipitated with 3 volumes of ethanol. After chilling at −70 °C the precipitate was collected, resuspended in 0.009 M Tris-Borate, pH 8.2, and 7 M urea. After heating in boiling water for 2 min, the samples were applied to a 12% acrylamide slab gel containing 0.09 M Tris-Borate, pH 8.2, 0.002 M EDTA and 7 M urea. The slab gels were run at 30 mA for 4 h or until the bromphenol blue marker had migrated 18 cm, and then autoradiographed. *a*, Transcription of whole operator fragments: the oligonucleotides contained in the numbered bands are listed in Table 1. *b* and *c*, Operator fragments were digested for 12 h with R.*Hind* II endonuclease. The products were separated by agarose acrylamide gel electrophoresis and used as templates for transcription primed by ApApA. The gel *b* shows the transcription product obtained from the larger cleavage product (approximately 80 base pairs). *c*, Shows transcription from the smaller R.*Hind* II product (approximately 30 base pairs) which contains the primary repressor binding site. The strong band near the bottom of this gel contains primarily AAAUGGUUG(C$_{OH}$), the product of incorrect priming, plus some AAAAUAGU(C$_{OH}$).

a primer. This property can be exploited to force the polymerase to initiate transcription at a given site by offering it an appropriate oligonucleotide primer[3].

The sequence information I had already obtained from unprimed transcription indicated that the operator contains a high degree of partial sequence reiteration. It was not easy therefore to find a short, unique sequence to use as primer. This problem was solved by the discovery that the polymerase has certain preferred initiation sites even on denatured DNA templates, possibly as a consequence of secondary structures assumed by the single strands. Although the sequence AAA occurs several times in the operator, the trinucleotide ApApA primes transcription starting almost exclusively at one site.

The product of ApApA primed transcription, fractionated by gel electrophoresis revealed another useful property of transcription under these conditions: the polymerase often terminates prematurely at a number of not entirely random sites, giving rise to a reproducible pattern of bands (Fig. 2a). Fingerprint analysis of these bands showed the progressive appearance of characteristic spots and facilitated the ordering of the corresponding oligonucleotides into a complete sequence. Table 1, shows the order of appearance of the oligonucleotides in the bands numbered in Fig. 2a.

Combined with nearest-neighbour analysis, these results established a probable sequence of 77 nucleotides starting with the primer ApApA. But, some details of the last 30 nucleotides remained open to alternative interpretations. These ambiguities were resolved by the observation that a minor component of the transcription product seemed to consist of sequences complementary to the principal product. Analysis of this complementary sequence resolved the ambiguities and established a sequence (Fig. 3). Surprisingly, this transcription is also primed by ApApA, initiating with AAACC... (the underlined nucleotides indicate the primer) and is clearly due to incorrect priming since the sequence should have only AACC. Transcription in the reverse direction was also obtained by priming with ApUpG, or with UpApG, yielding the sequences summarised in Fig. 3 and confirming the previous conclusions.

Location and orientation

The sequence of about 80 nucleotides shown in Fig. 3 represents the principal product of transcription primed with ApApA and, although the 3'OH end is not unique, it probably runs to the end of the operator fragment. The end is clearly somewhat ragged and can vary (at least) from position 3 to position −3 in Fig. 3 as some chains end with UpU$_{OH}$ and as priming with ApUpG starting from the end is possible in at least a fraction of the molecules.

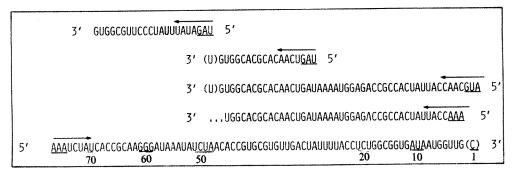
To determine the location and orientation of the sequence in the whole operator, I prepared smaller operator pieces by


Fig. 3 Summary of the sequences obtained by primed transcription. The figure shows the sequence of the principal primed transcription products discussed in the text. The underlined nucleotides indicate the priming sequence. The nucleotides are numbered starting from the most frequently observed terminus of the operator fragment. The next nucleotide, numbered −1 is the site of transcription initiation *in vivo* (see the following article).

Table 1 ApApA primed transcription of O_R fragments

Order of appearance of oligonucleotides in gel bands. Bands were cut out from the gels using the autoradiographs as a guide. The bands were extracted by soaking overnight in 1 ml 0.5 M NH_4OAc, 0.05% SDS and 30 µg tRNA. The extract was precipitated with 3 volumes of ethanol and the precipitate was digested with RNase T_1 or pancreatic RNase. Fingerprints were obtained by electrophoresis on cellulose acetate strips in the first dimension followed by homochromatography on DEAE–cellulose thin-layer plates[19]. The spots from the fingerprints were then analysed with RNase T_1, pancreatic RNase, RNase U_2 or alkaline hydrolysis as required. The table lists only the new oligonucleotides appearing in gel bands of increasing size, but omits the 3'OH terminals. Each band also contains the nucleotides of the preceding band. The underlined nucleotides indicate the primer. The nucleotides in parentheses were deduced from experiments in which only one of the four nucleotide tri phosphates was labelled. The labelled phosphate is transferred to the 3'OH end of the oligonucleotide which precedes it.

rebinding full size operator fragments with limiting amounts of repressor and redigesting the complex with pancreatic DNase. The resulting fragments were much shorter, ranging from about 30 to about 60 base pairs. They should still include the primary binding site but should have lost some of the weaker secondary sites. Transcription of these fragments, primed with ApApA, was initiated with the AAA at position 56 in the sequence shown in Fig. 3, indicating that it proceeds in the direction of the primary repressor binding site.

An alternative way to establish the orientation of the sequence is to localise it with respect to the R.*Hin*d II cleavage site. I treated full size operator fragments with *Hin*d II endonuclease, and separated the two products by gel electrophoresis. The larger fragment, approximately 80 base pairs long, transcribed with ApApA primer, yielded a sequence which is identical to that analysed in Table 1 but terminating with UpU_{OH} after 45 nucleotides (Figs 2b and 4). Transcription of the shorter fragment, approximately 30 base pairs long, with the same primer gave a mixture of products (Figs 2c and 4). Surprisingly, the major products are the result of incorrect priming: starting with AAAUG rather than with AAUG and with AAAC rather than with AAC. Priming at the AAAA site occurs less frequently and primarily starts with the first A rather than the second, yielding $\underline{AAA}AUAGU(C_{OH})$.

I conclude from these results that the sequence obtained begins in the distal one third of the operator and proceeds to the end proximal to the operon and including the primary repressor binding site. Further confirmation of this sequence was obtained by sequencing the RNA polymerase binding site associated with O_R as reported in the accompanying article[11].

Sequence features

The position of the R.*Hin*d II cleavage site acts as a point of reference for comparison with the sequence of the primary site of O_L (Fig. 5). In O_R, the R.*Hin*d II cleavage site has the sequence 5' GTTGAC 3'. This together with the results of others shows that the R.*Hin*d II recognition sequence GTpypuAC[12] includes all four combinations of py and pu and not only the complementary pairs. There are therefore three sequences recognised by this enzyme, since GTTGAC and GTCAAC are complementary and represent the same sequence. Another reference point is the transcription initiation site which in O_R is located at the nucleotide immediately following the C at position 1 in the sequence[11]. In O_R, as in O_L, the transcription initiation is located 33 nucleotides from the R.*Hin*d II cleavage site. With these reference points the O_L primary site sequence can be compared base for base with the O_R sequence.

The results of such a comparison are at present difficult to interpret. There is a high degree of homology between O_R and O_L and many sequences occur repeatedly in O_R. Such preservation or repetition of sequence features does not necessarily signify involvement in repressor recognition, however. It might be in part the result of recognition of other proteins (RNA polymerase, *tof* gene product) which interact with the same DNA region[14,15]. Or it might simply be due to the evolutionary process which gave rise to the multiple operators and preserved irrelevant sequence features as well as important ones. In what follows I present one of several possible schemes for interpreting the O_R sequence in terms of repressor binding sites.

By comparing the O_R sequence with that of the O_L primary

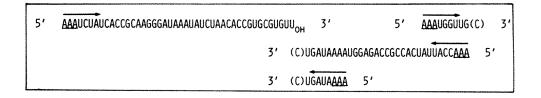
                                                        3'  (C)UGAUAAAA   5'
```


Fig. 4 Sequences obtained from the two O_R fragments produced by R.*Hin*d II cleavage. The sequence on the left represents the largest product of transcription of the larger R.*Hin*d II fragment. The sequences on the right, transcribed in both directions, are obtained from the smaller R.*Hin*d II fragment. Two of these sequences are due to incorrect priming of ApApA at sites containing only two As.
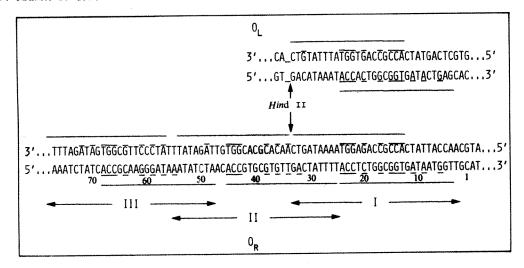

Fig. 5 Comparison of O_L and O_R sequences. Sequences in O_R comparable to the O_L sequence[5], are marked I, II and III. These partially overlapping regions are proposed as binding sites for repressor tetramers. The location of the dimers is represented by solid lines which are not intended to imply that each dimer recognises only one strand. The underlined nucleotides indicate sequence elements most nearly common to the eight dimer binding sites.

site, it is possible to single out three partially overlapping regions which present substantial sequence homology with each other and with O_L. These regions, labelled I, II and III in Fig. 5, are 30–35 base pairs long and each would correspond to a complete recognition site for a repressor oligomer, most likely a tetramer, given the size of the region involved and the structure of the repressor oligomer seen in the electron microscope (Brack and Pirrotta, unpublished). Region I, which has the highest degree of homology with O_L, is of course the primary binding site of O_R.

It has been pointed out that many recognition sequences in DNA contain a high degree of symmetry. The *lac* operator sequence contains an axis of partial twofold symmetry in which 16 out of 21 base pairs participate[3]. In the λ O_L sequence, Maniatis *et al.* have detected three such axes. In the three O_R regions which I propose, this kind of symmetry is also abundantly present. Three axes of twofold symmetry can be distinguished in region I, centred at positions 17, 18 and between 18 and 19. Similar axes occur in regions II and III at corresponding positions in their sequence. It is difficult to interpret these symmetries in terms of repressor recognition because the nucleotides involved are not always the same from one sequence to another. While this kind of symmetry would permit the formation of self-complementary loops as proposed by Gierer[17], experiments with superhelical DNA[4,18] have recently shown that such structures are not involved in repressor binding. It seems more likely instead that the symmetry of the recognition sequence simply reflects the symmetry of the protein interacting with it. Both the *lac* and the λ repressors are oligomers of identical subunits and may be reasonably expected to possess an axis of twofold symmetry. A possible binding scheme for λ repressor subunits, which exploits one set of symmetry axes and can account for the results of protection experiments, is the following.

We can image two repressor dimers binding to two regions about 21 nucleotides long and overlapping in the middle, nucleotides 4–24 and 13–33 respectively. These two regions are in fact related by a twofold axis of symmetry located between nucleotides 18 and 19, which would permit the two dimers to recognise similar sequences on opposite strands. In the O_L sequence, this interpretation would account for the second of the axes of symmetry detected by Maniatis *et al.*[5]. An additional dimer binding to O_R would occupy the region between nucleotides 25 and 45: the first half of region II. This arrangement would protect against nuclease digestion a region of approximately 45 base pairs corresponding to the $S_1 + S_2$ fragment reported by Maniatis and Ptashne[4]. Region II is the one with the lowest degree of homology with the O_L

sequence. We may expect that repressor binding to this site is weakest and stabilised only by interaction with the repressor bound at the primary site. Binding of additional repressor dimers would then fill the remaining sites, progressively increasing the size of the protected region in steps of approximately 15 base pairs. At each step, the partial overlap of the sites would permit interaction of a dimer with the preceding one.

This model yields eight sequences, two from O_L and six from O_R, which are now known and which would constitute binding sites for repressor dimers. While differing in many details, these sequences have certain features, underlined in Fig. 5, which remain remarkably constant and are nearly common to all eight proposed binding sites. According to this model, these nucleotides are therefore the most likely candidates for repressor recognition elements and for the sites of operator constitutive mutations. The only such mutation so far identified is in fact located at position 24 in O_L (ref. 5).

It will be of great interest to see whether the sequence of the remaining sites of O_R and O_L conforms to this pattern and whether other operator mutations are in fact located as predicted by the model.

Sequence of the P_R promoter of phage λ

Alfred Walz & Vincenzo Pirrotta

Department of Microbiology, Biozentrum der Universität Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland

The RNA polymerase binding site from the λ P_R promoter was isolated and sequenced. This DNA fragment contains the transcription initiation site and shares 25 nucleotides with O_R. The sequence preceding the initiation site suggests that the promoter recognition site is not identical with the tight binding and initiation site.

THE promoter has been loosely defined as the site on the DNA where the RNA polymerase recognises some signal which allows it to bind tightly and initiate transcription. There are several such physiologically significant sites in the DNA of phage λ, two of which are the early promoters controlled by the repressor and governing transcription of the early genes, to the right and to the left of the two operators. Genetically these promoters are located very near the operators. Some promoter mutations have been mapped between known operator mutations, suggesting that the two sites may overlap[1]. Allet and Solem[2] and Maurer *et al.*[3] have shown that certain promoter mutations alter a recognition site for the *Hind* II restriction endonuclease, which is located about 30 base pairs inside the operator. This finding implies that the operator and promoter overlap at least partially.

In the *lac* operon, the polymerase initiates transcription at the distal end of the operator and the mRNA produced contains the operator sequence[4,5], whereas in λ this is not the case. It has been shown, at least for the left-hand operon, that transcription initiates outside the immunity region[6] and in fact immediately outside the primary repressor binding site[7].

One approach to the study of the promoter has been to isolate the region of DNA with which the polymerase forms a stable complex. At temperatures above 20 °C, RNA polymerase binds extremely tightly to promoter sites, forming the so-called "open complexes" from which it is able to initiate transcription[8]. This tight binding has been exploited to isolate DNA fragments protected by RNA polymerase against nuclease digestion[9,10].

We have used the same approach to isolate a polymerase protected fragment from the vicinity of the λ O_R operator. Here we report the isolation and properties of this fragment and its sequence, obtained by primed transcription of the isolated fragment.

Isolation of polymerase protected fragments

To minimise nonspecific polymerase binding we used as starting material DNA fragments from the immediate vicinity of O_R. These fragments were obtained by sonicating the DNA of λ d*bio* M30-7, a phage containing only the right-hand operator, and selecting the operator-containing pieces by binding them' with repressor and trapping them on a nitrocellulose membrane filter. We then added RNA polymerase holoenzyme in limiting

Fig. 1 Gel electrophoresis of RNA polymerase protected fragments. Operator-containing fragments were preselected from 500 μg sonicated λd*bio* M30-7 DNA labelled with [32]P, by binding with λ repressor and filtering through a membrane filter[11]. 5 μg RNA polymerase holoenzyme were added to the preselected fragments in buffer containing 0.05 M Tris, pH 7.9, 0.1 M KCl, 0.01 M $MgCl_2$, 0.1 mM EDTA, 0.1 mM dithioerythritol and 5% glycerol. After 10 min at 37 °C, pancreatic DNase was added to a concentration of 100–200 μg ml⁻¹ and incubation continued for another 10 min. If the KCl concentration was higher than 0.1 M, the DNase was not sufficiently active unless the reaction mixture was diluted. The digestion was stopped by addition of excess EDTA immediately followed by a phenol extraction and precipitation with 2 volumes of ethanol. The precipitate was resuspended and applied to a 10.4% acrylamide –0.7% agarose gel made up in 0.09 M Tris-Borate, pH 8.2, and 2.5 mM EDTA. After electrophoresis for 2 h at 25 mA, the gel was autoradiographed. *a*, RNA polymerase protected fragments; *b*, heat denatured protected fragments; *c*, operator fragments of mixed sizes prepared as previously described[11]; *d*, product of digestion of operator fragments in the presence of excess RNA polymerase. The polymerase does not protect any part of the operator in these conditions.

Fig. 2 Gel electrophoresis of transcription initiated on RNA polymerase–DNA complexes. Complexes of RNA polymerase and preselected DNA fragments were prepared and digested with pancreatic DNase as in Fig. 1. After 10 min of digestion at 37 °C, 3 unlabelled NTPs were added to the same mixture at a concentration of 0.2 mM and the fourth, α-[32]P labelled at 100 mCi μmol⁻¹, and a concentration of 5 μM. After incubation for 0.5–2 min, the reaction was stopped by adding excess EDTA and precipitating with 3 volumes ethanol. The precipitate, resuspended in 0.009 M Tris-Borate–7 M urea, was heated in boiling water for 2 min and applied to a 12% acrylamide slab gel containing 7 M urea and electrophoresed as described in ref. 14.

Table 1 Transcription initiation sequence

Pancreatic RNase	RNase T$_1$
pppAU (G), GU (A), AC (U),	pppAUG (U), UACUAAG (G),
U (A), AAGGAGGU (U), U (G)	G (A), AG (G), G (U), UUG
pppAUGUACUAAGGAGGUUG	

Bands were cut out from the slab gel and extracted as described previously[14]. The band contents were digested with pancreatic RNase and RNase T$_1$ and the products separated by electrophoresis on cellulose acetate pH 3.6 in the first dimension, followed by chromatography on PEI cellulose thin layers with 2.5 M pyridine formate pH 3.5 and 7 M urea. The sequence of the oligonucleotides were determined by analysis with pancreatic RNase, RNase T$_1$, and by nearest-neighbour information (represented in parentheses).

amounts and digested the resulting complex with pancreatic DNase. The digestion was stopped by a phenol extraction, and the DNA fragments protected against digestion, which we will refer to as polymerase-protected or P-fragments, were then precipitated with ethanol and analysed by gel electrophoresis. The P-fragments migrated as double stranded DNA about 40–45 base pairs long (Fig. 1). Heat denatured P-fragments migrate faster and are clearly distinguishable. While isolated λ operator fragments can be shown to rebind well to repressor[11,12], the P-fragments do not rebind to RNA polymerase. Nor could we demonstrate binding of repressor to the P-fragment. Furthermore, polymerase could not protect any part of the isolated operator fragments against DNase digestion. Treatment of the P-fragments with the *Hin*d II endonuclease produced no detectable change in size. While these are all negative results, taken together they suggest that if there is overlap between the repressor binding site and the polymerase binding site, it is only partial and does not extend as far as the R. *Hin*d II cleavage site.

Transcription initiation site

The RNA polymerase protected fragment contains the initiation site for transcription. We treated the polymerase–DNA complex as before with pancreatic DNase but we then added the nucleotide triphosphates to initiate transcription in the same reaction mixture. As the polymerase starts transcribing, it exposes the protected DNA to digestion by the DNase. Each polymerase complex can therefore initiate only once and from a unique site in the protected fragment. On gel electrophoresis the transcription product consists of two bands differing in length only by a few nucleotides. The largest product is 17–18 nucleotides long (Fig. 2). The fingerprints show that the two bands represent a unique sequence initiating with pppAUG (Table 1) and corresponding to the sequence of the normal transcription initiation from P$_R$ observed both *in vivo* and *in vitro*[6].

We conclude that, as was previously observed by Schaller *et al.*[13] with fd RF DNA, the site at which the RNA polymerase forms the tight complex is also the site from which it initiates transcription and that the active site of the polymerase is located at about one-third of the total distance covered by the enzyme bound to the DNA.

Primed transcription

To sequence the remaining part of the polymerase binding site we used again the RNA polymerase but this time forced transcription of the isolated protected fragments using di- or trinucleotide primers and a denatured template. Since the initiation sequence in Table 1 contains two GG sites, we used CpC as a primer, hoping to obtain transcription in the opposite direction. Gel electrophoresis of the transcription product separated several bands which, when analysed with RNase T$_1$, proved to represent a single growing chain (Fig. 3 and Table 2). The last oligonucleotides to appear corresponded to those found in the transcription initiation sequence in Table 1, showing that, contrary to our expectation, the CpC was priming in the same direction but starting near the other end of the protected fragment. The order of appearance of the RNase T$_1$ and pancreatic RNase oligonucleotides, together with nearest-neighbour information, sufficed to establish a sequence of 40 nucleotides, starting with the CpC primer and ending with the transcription initiation sequence. Since the entire protected fragment is 40–45 base pairs in length, no more than five nucleotides could still be missing. To determine these and to confirm the sequence, we attempted again to prime transcription in the opposite direction, using this time ApUpG as a primer. This primer in fact gave transcription in both directions, separable by gel electrophoresis and made it possible for us to add a maximum of three additional nucleotides to the sequence (Table 3). These were not always present and probably repesent the ragged ends left by the pancreatic DNase treatment used to prepare the protected fragments.

The promoter–operator region

The sequence we have obtained for the RNA polymerase binding site shares about 25 nucleotide pairs with the sequence of the primary repressor binding site of the λ O$_R$ operator[14]. Only the transcription initiation sequence is unique to the polymerase site (Fig. 4). The overlap between operator and polymerase site is therefore only partial and does not extend to the region recognised by the *Hin*d II endonuclease. How can we reconcile these findings with the observation that promoter mutations are located in the R. *Hin*d II site and that polymerase bound to λ DNA prevents the *Hin*d II enzyme from cleaving the operators[2,3]? We note that the latter effect was observed at a molar ratio of 30 polymerase per DNA, and could be easily explained by steric hindrance preventing the approach of the *Hin*d II enzyme or by multiple binding of polymerase in the promoter region[16]. The former observation however, implies that the polymerase recognises a region including the R. *Hin*d II sequence. It is unlikely that it could do so while bound at the initiation site since the polymerase molecule itself, as seen in the electron microscope, is not longer than the 40 base pair region it protects (Brack, personal communication). One possible explanation is that the polymerase requires additional sequence elements for recognition and 'entry' into the DNA. This would explain why the isolated protected fragments do not have

Table 2 Sequence of CpC primed transcription

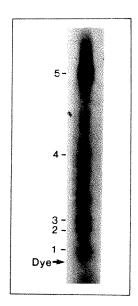
Bands were cut out from the gel in Fig. 3 and fingerprinted as described in Table 1. Only the new oligonucleotides appearing in each band are listed. Each band contains also the oligonucleotides of the preceding band. The underlined nucleotides indicate the primer sequence.


Fig. 3 Gel electrophoresis of primed transcription. RNA polymerase protected fragments were prepared as described in Fig. 1 and used as templates for transcription primed with CpC. The details of the transcription reaction and urea gel electrophoresis were as described in ref. 14. The oligonucleotide composition of the numbered bands is shown in Table 2.

appreciable affinity for RNA polymerase. We propose then that recognition, entry, tight binding and finally initiation are different elements of the polymerase–promoter interaction which need not occur at exactly the same site. The last two events clearly take place at the site whose sequence we report here. The site for the first and second events must be looked for further inside the operator sequence. In this region, however, it is difficult to discern which structural features of the sequence result from the repressor binding function and which result from the polymerase recognition. Nevertheless, by comparison with the sequence of other promoter regions we can discern two common features: First the presence of one or more AAAT sequences, and second, regions of very high GC content flanking a region of very high AT content.

Similar features have been noted in the *lac* promoter region (5) and in that of the tRNA^{Tyr} gene [16] and it has been suggested that they may be involved in the recognition and entry process. Furthermore, if the λ operator–promoter sequence is aligned with that of the lac promoter–operator region using the transcription initiation site as a reference, the GC and AT-rich regions are almost exactly in register and 22 base pairs out of 48 are identical. We suppose that a loose complex is formed by the

polymerase at the recognition or entry site. Transition of thi: loose complex to an 'open complex' might result from the open ing of some 6 base pairs, in the AT-rich region. The tight bind ing, however, occurs only when the polymerase shifts from the entry site to the binding or initiation site. This shift must occur fairly rapidly after 'opening' of the promoter and does not require the presence of the nucleotide triphosphates. We anticipate that, in the appropriate conditions, it should be possible to block the polymerase at the recognition or entry site and identify the sequence involved. Dickson *et al.*[5] have proposed a similar model for the *lac* promoter. They suggested that the role of the GC-rich regions might be to act as a "transducer"; that is to transmit the helix destabilisation produced by the catabolite gene activator protein (CAP) bound to the region immediately adjacent to the GC-rich region and so facilitate entry by the polymerase. The fact that the λ P_R promoter has the same GC–AT–GC structure even though it is not regulated by the CAP protein suggests that this structure may be a more general feature of polymerase recognition sequences. We note that in the P_R sequence the GC region contains only 73% GC rather than 83% as in the *lac* region. This difference might be enough to make polymerase entry into th λ P_R promoter possible without additional facilitation. It is possible that the transition temperature to an 'open' RNA polymerase–promoter complex is related to the GC content of the regions flanking at the AT-rich region.

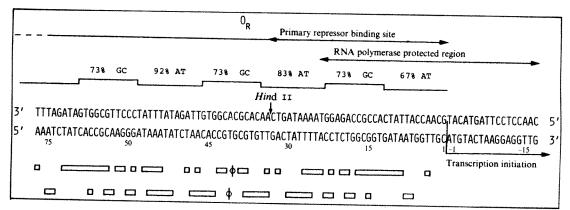
Finally, we would like to point out an additional feature of the promoter–operator region, which may be significant. The sequence contains three blocks of high GC content alternating with two blocks of high AT content. Furthermore, two axes of relatively high partial symmetry are located at, or adjacent to, nucleotide 41 (Fig. 4). These two observations suggest the possibility that there may be two polymerase recognition or entry sites in this region, both composed of two GC-rich regions surrounding an AT-rich region. The two sites would share one GC-rich block, and, because of the rotational symmetry, would be oppositely oriented. We know in fact, that there exists a promoter for leftward transcription in this region. The P_{rm} or repression maintenance promoter is a weak promoter responsible for transcription of the λ C_1 or repressor gene in a lysogenic cell[17]. A mutation in this promoter has been localised in the region of nucleotides 48–54 in the O_R sequence (Hedgpeth and Smith, personal communication). Furthermore, *in vivo*, functioning of this promoter requires the presence of active repressor[17,18]. If the region between nucleotides 35 and 71 is in fact the recognition–entry site of this promoter, we can easily explain this requirement. P_R is a strong promoter: it has a high affinity for polymerase. Polymerase binding at the P_R recognition site is incompatible with binding at the P_{rm} site. Hence, in the absence of repressor, P_R transcription predominates. In the presence of repressor, P_R is pre-empted by repressor bound at the primary site of O_R, occupying the region 1–33 in the sequence.


Fig. 4 Promoter–operator sequence from the O_R region. The RNA sequences are written as DNA. The regions of high GC and high AT content are marked above the sequence. The bars below the sequence indicate complementary sequences located symmetrically with respect to two possible axes of symmetry at or adjacent to nucleotide 41.

Table 3 Sequence of ApUpG primed transcription

The sequence of the largest T$_1$ oligonucleotide was not determined in detail but was deduced by pancreatic RNase analysis and from the sequence of the complementary strand.

This leaves P$_{rm}$ available to polymerase for transcription of the C$_1$ gene. If excess repressor is present, the additional repressor binding sites will begin to be occupied, pre-empting also P$_{rm}$ and therefore regulating by negative feedback the transcription of the repressor gene itself. A prediction generated by this model is that if the P$_R$ site is blocked by suitable amounts of repressor, or better, by cleavage with R. *Hin*d II it should be possible to detect leftward transcription *in vitro* of the O$_R$–C$_1$ region starting at the P$_{rm}$ site.

We thank Kurt Ineichen and Carol Bentley for technical assistance. This work was supported in part by a grant from the Swiss National Foundation for Scientific Research.

Enhancement of the electrical excitability of neuroblastoma cells by valinomycin

Ilan Spector, Clive Palfrey & Uriel Z. Littauer

Department of Biochemistry, The Weizmann Institute of Science, Rehovot, Israel

Mouse neuroblastoma cells in stationary phase of growth display partially developed electrical properties. Addition of the K$^+$ selective carrier valinomycin to these cells causes rapid enhancement of electrical excitability. We suggest that the appearance of molecules with properties similar to valinomycin is essential for the full expression of electrical excitability in differentiating neuroblastoma.

MACROCYCLIC antibiotics and related compounds which can selectively translocate ions in artificial and biological membranes, have been used to explore the molecular basis of cellular ion permeation[1-3]. The natural occurrence of ionophores in biological membranes has been reported[4,5] and supports the speculation that cyclic molecules, especially those with valinomycin-like properties, may provide the natural basis for resting membrane permeability in some tissues[3,6]. The application of compounds such as valinomycin to electrically excitable membranes, however, either did not produce detectable permeability changes[7-9], or gave rise to an impairment of electrical function[7,10,11]. As the membranes already studied possessed highly specific permeability properties, we wished to investigate an excitable system in which resting and active selectivity patterns are not fully established. Mouse C-1300 neuroblastoma, from which many clonal lines have been isolated[12,13], is particularly suitable. Cells from several lines can generate well developed action potentials after long term treatment with certain agents such as aminopterin or

dibutyryl cyclic AMP(db-cyclic AMP)[14-16], but as we show here, if these cells are maintained in the stationary phase of growth, excitability is only partially expressed. The transition from partial to full excitability, a process normally taking 1–3 weeks, includes a rise in resting potential, membrane resistivity and action potential currents. Here we show that a comparable change in electrical properties can be rapidly induced by the addition to the culture medium of low concentration of valinomycin.

Properties of stationary phase cells

Electrophysiological experiments were performed on clone N1E-115 cells in stationary phase of growth using previously described techniques for intracellular microelectrode recording[15]. Because the confluent cell population is somewhat heterogeneous, only large cells of diameter of 70–100 µm with a marked degree of process formation were studied (see Fig. 3a). As summarised in Table 1, transmembrane resting potentials and input membrane resistances were relatively low for most of these cells. When equal depolarising and hyperpolarising current pulses were applied at the resting potential, most cells showed delayed rectification, that is, smaller resistance with depolarising than with hyperpolarising pulses[17]. Figure 1a shows that with sufficiently large depolarising pulses, the elicited voltage reached a maximum, then gradually declined to a plateau 2–8 mV below the peak. As shown in Fig. 2 increments in the intensity of the depolarising pulse gave only slight

Table 1 Effects of valinomycin on electrical properties of stationary phase NIE-115 neuroblastoma cells

	Membrane potential (−mV)*	Membrane resistance (MΩ)	Time constant (ms)	Max. dV/dt spike (V s⁻¹) rise	fall	Potential at spike peak (mV)	Amplitude of fall phase (mV)	n
Control	16.4±1.4	5.5±0.5	7.8±1.0	21.1±2.9	2.3±0.4	7.6±1.7	20±1.0	37
Valinomycin treated (10⁻⁶–10⁻⁸ M)	34.3±3.8	12.5±1.8	15.3±2.1	53.6±6.8	28.5±3.2	24.7±2.0	52.5±2.0	16

Cultures were grown to confluency in Dulbecco–Vogt modified Eagle's MEM (DMEM) (GIBCO), supplemented with 10% foetal calf serum (FCS) (GIBCO) in Falcon plastic flasks. For electrophysiological studies, cells that were maintained in confluency for at least 2–4 weeks with daily changes of medium were washed twice with Puck's saline D1 and then treated with D1 containing 0.05% trypsin for 5 min. After resuspension in fresh DMEM+FCS, 5×10^5 cells were seeded per 60 mm Falcon tissue culture dish (2.4×10^4/cm²). The replated cells passed through a lag period of 4–5 d before cell division recommenced; this continued for 4–5 d until cells reached a high density confluent state (3×10^6 cells per 60 mm dish, or 1.9×10^5 cells cm⁻²). Electrical studies were made on both lag and confluent cells, their electrical properties were found to be similar. In parallel, cells from the same flasks were plated at a similar density for determination of intracellular ionic concentration by atomic absorption spectrophotometry (in preparation). Stock solutions of valinomycin (Calbiochem) at 10⁻³M were prepared in 100% ethanol, and diluted on the day of the experiment at least 1,000-fold to the concentration used in the experimental media. The ethanol concentration which never exceeded 0.2% was found to have no effect on the electrical properties of neuroblastoma cells. In the present set of experiments the membrane was exposed to a concentration of 10⁻⁸ M valinomycin after recordings were obtained from cells in normal medium. In one of two valinomycin batches used, the initial concentration of 10⁻⁸ M was found to be effective. But in the second batch, the effective concentration was 10⁻⁶M. Similar differences in valinomycin activity between batches have been seen previously and result most probably from deterioration[3,20,21].

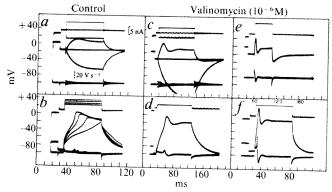
Intracellular microelectrode recordings were made in the culture dish which was held in a special chamber on the stage of an inverted phase contrast microscope with control of temperature between 36 and 38 °C. The pH was maintained between 7.2 and 7.4 by passing a constant stream of warmed 5% CO_2 in air over the dish. The cultures were bathed in the growth medium which contained the following salt concentrations in mmol l⁻¹: NaCl-109.5; KCl-5.5; CaCl₂-1.8; MgSO₄-0.8; NaHCO₃-14.4; NaH₂PO₄-0.9. 3M-KCl micropipettes with resistance ranging from 10–20 MΩ were used. They were arranged in the bridge circuit of a Bioelectric P system to allow stimulation of the cells through the recording pipette. The transmembrane voltage and stimulating currents as well as the electronically derived time derivative of transmembrane voltage were displayed on an oscilloscope and photographed. When a stable resting membrane potential had been reached, input membrane resistance and an estimate of membrane time constant were determined using comparable hyperpolarising current pulses. Determinations of active membrane properties were made on cells adjusted to a standard membrane potential level of −95±5mV. This gives a nearly maximal rate of rise and eliminates variation as a result of differences in initial resting potential. Ionic currents flowing during an evoked action potential were quantitatively estimated from the maximum value of the time derivative of the transmembrane potential (maximum dV/dt)[15]. Responses were also measured in terms of the differences between the maximum membrane depolarisation evoked by the stimulating pulse and the adjusted steady membrane potential (potential at spike peak). Positive values of this measure indicate action potential overshooting zero potential.
*Values in all columns are given as mean±s.e.


Fig. 1 The effects of valinomycin on the electrical activity of stationary-phase neuroblastoma NIE-115 cells. *a* and *b*, control records; *c* and *d*, *e* and *f*, examples of responses in the presence of valinomycin. All records are from the same dish; cells were replated 12 d before experiment. In this and subsequent figures the uppermost trace represents the injected current, inward current shown as downward deflection; the middle trace represents the transmembrane potential recorded in a bridge circuit; the lowest trace represents the time derivative of the transmembrane potential (dV/dt). Current and dV/dt calibration bars (in *a*) apply to all records. A 10 ms, 20 mV voltage calibration pulse is seen at the left of the middle traces. Records *a* and *c* represent the voltage responses to depolarising and hyperpolarising current pulses applied at the resting potential of each cell. Note that in the presence of valinomycin a smaller current intensity elicits a much larger hyperpolarising potential. In *e* an outward pulse was applied at a steady membrane potential adjusted to that of the control cell. Note the fast declining phase and hyperpolarising after potential. In *b*, *d* and *f* the steady membrane potential was adjusted to −100 mV to obtain maximal action potentials. Note that in the control (*b*), the slow time course of the falling phase is not affected by increments in the intensity of the applied current, whereas the rise rate is slightly increased; in *d* a stimulus at the threshold level was applied to show that after valinomycin treatment rise rates comparable with those in the control determine faster fall rates; *f*, a fast rising, short duration action potential followed by a slowly rising peak elicited by a larger stimulus in the presence of valinomycin.

changes in the steady potential level, whereas an almost linear current–voltage (I–V) relationship was obtained for inward currents. Few cells showed anomalous (inward-going) rectification (Fig. 3*b*)[18], or ohmic behaviour throughout the explored range.

Active membrane properties were assessed by applying depolarising current pulses at a membrane potential preset to a standard level of −95±5 mV. Under these conditions, all cells tested generated action potentials. As shown in Table 1 and Fig. 1*b*, the amplitude and rate of change of both rising and falling phases were generally low, and overshoot potentials could not always be recorded.

The electrical properties just described contrast strongly with the well developed properties obtained after long term cell selection with aminopterin or db-cyclic AMP[15,16], suggesting that a major step which is required for full expression of electrical excitability does not take place in stationary phase cells. This step may involve a change in the permeability properties of the membrane. If this change includes an increase in K⁺ permeability (P_K), it seemed possible that valinomycin, a K⁺ selective carrier[19–23], could rapidly produce an enhancement of electrical excitability.

Effect of valinomycin on passive and active membrane properties

Table 1 compares electrical properties of cells before and after treatment with valinomycin. Steady state conditions were attained about 10 min after exposure to valinomycin and remained constant for experimental periods of at least 4 h. As shown, a concentration as low as 10⁻⁸ M produced a twofold increase in average resting potential accompanied by a similar increment in input membrane resistance and a dramatic enhancement of electrical excitability.

In terms of the constant-field equation[24,25] an increase in P_K which lowers the permeability ratios P_{Na}/P_K or P_{Cl}/P_K or both can explain the observed increase in resting potential provided

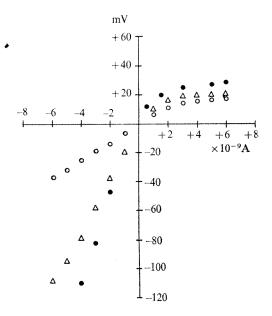
mV


Fig. 2 Steady-state current–voltage (I–V) relationships in stationary-phase N1E-115 cells. ○, Before; ●, after addition of valinomycin (10^{-8}M) to the culture medium. Cells were replated 3 d before the experiment. △, I–V curve of a cell grown for 18 d in a culture medium containing aminopterin (10^{-7} M). The points represent the amplitude of the potential 150 ms after the start of the current pulse. Zero on the voltage axis corresponds to the resting potential of each cell which was −34 mV in all cases.

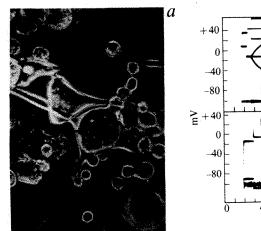
hat the internal K^+ level remains constant. Preliminary measurements of intracellular K^+ concentration in replicate plates before and after 1 h incubation with 10^{-8} M valinomycin suggest that the antibiotic does not significantly alter the internal level of this ion, in both cases values of 155 ± 5 mM were obtained.


Using this value against an external K^+ concentration of 5.5 mM, an equilibrium potential for K^+ (E_K) of approximately −89 mV is obtained with the Nernst equation. This figure is substantially higher than that obtained experimentally for valinomycin-treated cells (mean value −34 mV) or that seen by us in aminopterin-selected cells (mean value −38 mV), and suggests that Na^+ and/or Cl^- ions continue to play a role in determining the resting potential.

If the hyperpolarisation of the membrane potential reflects an increase in P_K alone, then it should be paralleled by a rise in total resting membrane conductance, that is, by a fall in membrane resistance. Table 1 shows that valinomycin induces a twofold increase in the average input resistance. Thus, the steady-state I–V curve in the presence of valinomycin, resembling that obtained after aminopterin selection, exhibits a much steeper slope in the hyperpolarising direction (Fig. 2). Furthermore, although the voltage response evoked by a depolarising pulse was generally somewhat increased, as is illustrated in Fig. 3 all cells displayed delayed rectification. The unexpected increase in resistance indicates an overall diminution in the total number of passively conducting pathways. The most likely interpretation for this effect is that the fraction of membrane conductance contributed by Na^+ or Cl^- ions or both is lowered to an even greater extent than the increase in K^+ conductance.

The valinomycin induced changes in active membrane properties were of similar complexity. At membrane potentials positive to the threshold for spike initiation, when a depolarising stimulus elicited an early peak which declined to a steady-state level, valinomycin markedly increased the rate and amplitude of the decline (Fig. 1e). When spikes were initiated from the same hyperpolarised membrane potential as that of the control, the falling phase in particular exhibited a remarkable increase in both amplitude and maximum dV/dt (Table 1). This usually led to a considerable shortening in spike duration and to the appearance of an otherwise masked second, slowly rising peak (Fig. 1f). As the falling phase of the action potential is caused by an increased permeability to K^+ ions these results can be accounted for by an increased translocation of the valinomycin-K^+ complex across the excited membrane.

As shown in Table 1, valinomycin also had dramatic effects on the amplitude and rate of change of the depolarising phase. The current during this phase is carried by two systems: a tetrodotoxin (TTX)-sensitive, fast conducting Na^+ system, and a TTX-insensitive, slow conducting Ca^{2+} system[15]. The generally low maximum dV/dt values obtained with stationary cells indicate that the fast conducting Na^+ system is poorly developed at this stage. The significant increase in rise rates suggests therefore that valinomycin activates membrane elements involved in fast inward movement of Na^+ ions.

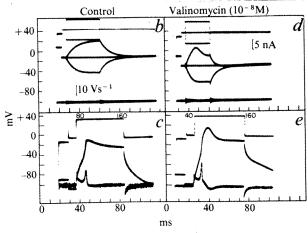
Estimation of the threshold potential for spike initiation from the inflection point between the slowly rising electrotonic potential and the upstroke of the action potential gave a value of about


Fig. 3 Electrical activity from the same neuroblastoma cell before and after valinomycin treatment, *a*, Phase contrast photomicrograph of cells from a 'confluent' culture replated 24 d before experiment. All records were obtained from the cell designated by an arrow in *a*. Voltage responses to depolarising and hyperpolarising current pulses applied at the resting potential of the cell are presented before (*b*), and after (*d*), addition of valinomycin (10^{-8}) to the bath. Note the anomalous rectification before treatment and the delayed rectification in the presence of valinomycin. Action potentials are presented in records *c* and *e* before and after valinomycin treatment, respectively. In both cases the steady membrane potential was adjusted to about −100 mV to obtain maximal responses. Note that in the presence of valinomycin, maximum dV/dt and amplitude of both the rising and falling phases of the action potential were markedly increased. dV/dt calibration bar in *b* applies to *c*, *d* and *e*.

−40 mV both before and after treatment, so the rise in peak overshoot after valinomycin treatment represents an absolute increase in spike amplitude. Such an increase can be accounted for either by a change in electrochemical driving force for Na⁺ ions, or by an increase in the voltage-dependent changes in Na⁺ permeability during the upstroke of the action potential. Preliminary measurements of intracellular Na⁺ concentration gave a value of 35 mM before treatment which declined to 27 mM after 1 h incubation with 10^{-8} M valinomycin. Calculating E_{Na} from the Nernst equation with these figures, against an external concentration of 124.8 mM, gives values of $+34$ and $+41$ mV respectively. Because such a small increase in E_{Na} cannot account for the large differences in peak action potential amplitudes before and after valinomycin treatment, it seems that a change in the rate at which membrane permeability to Na⁺ increases during spike activity is involved.

Mode of action

Although the increase in resting potential and the enhanced repolarising electrogenesis can be easily rationalised on the basis of the known properties of valinomycin as a selective carrier of K⁺, the closing of passively conducting ionic pathways and the activation of membrane elements involved in the fast inward movement of Na⁺ ions, underline the possibility that a structural rearrangement of the membrane takes place. This may include a modification of membrane structure by valinomycin unrelated to its ionophoric function. It is also possible that the ionic selectivity characteristics of the antibiotic could be modified by such determinants of membrane organisation as surface charges, dipoles and fluidity[26]. Nevertheless, the striking similarity between the electrical properties of valinomycin-treated cells and those selected by long term incubation in aminopterin or db-cyclic AMP[14-16] and the fact that changes in K⁺ permeability seem to play a major role in many other developing cellular systems[27-30], strongly suggest that this permeability change is responsible for the rearrangement of the neuroblastoma membrane. If so, this phenomenon could shed some light on the temporal relationship between surface membrane permeability changes and other events that take place during development[31,32]. That such changes in neuroblastoma can be so rapidly triggered by valinomycin

leads us to propose that during the differentiation of these cells molecules with properties similar to those of valinomycin appear. These molecules are responsible for the induction of K⁺ permeability, an event which seems to be crucial for the full expression of electrical excitability.

Non-variable 13.5 mm flux in the strong millimetre component of Centaurus A

IT has been suggested[1] that the peculiar galaxy and strong radio source Cen A has a strong and possibly variable component in the millimetre wavelength region.

Our observations do not support this claim. The evidence of variability was based on two measurements made at 3.4 mm and one at 9.5 mm at the 36-foot telescope of the National Radio Astronomy Observatory. Observations made at the position of the strong infrared source[2] were carefully calibrated against the sources of known intensity: Mars, Saturn and DR21. An important consideration in these observations was the relatively large correction for the atmospheric attenuation. At the NRAO site, Cen A has a maximum elevation of 15°. The atmospheric attenuation factor at the position of the source, $\exp(\tau)$, was about 1.5. The March 1974 measurements at 3.4 mm gave

results of 22.5 ± 2.0 Jy and 14.0 ± 1.5 Jy, and the result at 9.5 mm was 23.7 ± 2.0 Jy. If the errors cited are realistic estimates, the statistical significance of the detection of variability is very high.

We have made 18 measurements of Cen A at the position of the infrared source at a wavelength of 13.5 mm on nine days between April and December 1974. The observations were made with the 13.7-m radio telescope of the Itapetinga Radio Observatory[3]. The results of our observations of the flux density F_v are given in Table 1 with the $1-\sigma$ statistical errors, s. We also present the observations of the reference source, Virgo A, which is assumed to have a flux density of 21.4 Jy at this wavelength[4]. Although the zenith attenuation at this wavelength is greater than that cited for the NRAO work, the source is much more favourably placed in the sky for observations at Sao Paulo. The atmospheric attenuation factor was comparable to the value cited for NRAO and varied between 1.2 and 1.5.

Table 1 Flux density of Cen A and Virgo A (Jy)

Date (1974)	$F_{V_{Cen}} \pm s_{Cen}$	$F_{V_{Vir}} \pm s_{Vir}$	$r \pm s$
April 30	19 7±0 4	20 5±0 5	0 962±0 032
May 7	21 6±0 7	20 9±0 5	1 034±0 041
May 14	21 5±1 5	20 4±0 3	1 056±0 076
May 20	24 5±0 6	24 3±0 6	1 008±0 034
June 3	21 6±0 8	20 9±0 1	1 031±0 040
November 8	22 5±0 9	20 6±0 8	1 089±0 059
November 28	21 9±1 2	20 1±1 0	1 089±0 078
November 29	22 5±0 6	24 7±1 2	0 914±0 052
December 6	20 3±0 4	20 3±0 3	1 000±0 026

In Table 1 we also give the ratio r of the flux density of Cen A and Virgo A, the error s of the ratio is given by[5]

$$s^2 = s^2_{Cen}/F^2_{V_{Vir}} + [(F_{V_{Cen}}/F_{V_{Vir}})^4 (s^2_{Vir}/F^2_{V_{Cen}})]$$

A cursory inspection of the values of the ratio indicates that we have no evidence for variability at this wavelength during the times that these observations were made A simple statistical analysis equivalent to the analysis given by Fogarty *et al*[6] confirms that there is no statistical significance for the suggestion that the source might have a variable flux density at 13 5 mm

If, as it seems from our data and those of Kellermann[1], the source is variable at 3 4 mm but not variable at 13 5 mm, there must be some strongly wavelength-dependent radiation mechanism which enables the source to decrease its intensity at 3 4 mm with a very short time scale, while remaining constant at 13 5 mm

We note that the flux density of this source is approximately constant, $\approx$ 22 Jy, over the wavelength range from 3 4 mm to 13 5 mm So another interpretation of the observations is that the one measurement by Kellermann[1] of 14 0±1 5 Jy on March 28, 1974, is in error and that the source is strong but not variable

Optical variation of 3C371

WHILE studying the nucleus of 3C446 Cannon and Penston[1] put forward a hypothesis involving a small continuous source of constant luminosity which may be temporarily obscured by absorbing clouds This hypothesis is supported by our observations[2] of the nucleus of the N-galaxy 3C371, which reveal variations of its luminosity during a characteristic time of $t = 40$ min, or $2 4 \times 10^3$ s

The light curve taken on September 12, 1972, resembles those of eclipsing binary stars (Fig 1) M I Lavrov of the Kazan University (USSR) suggested (personal communication) that the luminosity changes seem to be similar to the luminosity variation of Algol It may be supposed that QSO nuclei, the nuclei of Seyfert galaxies, the nuclei of N-galaxies and other compact extragalactic objects have two or more components rotating around a common centre of gravity In this case the radius of these objects could be less than a limit given by

$$ct = (3 \times 10^{10} \text{ cm s}^{-1}) \times (2 4 \times 10^3 \text{ s})$$
$$= 7 2 \times 10^{13} \text{ cm}$$

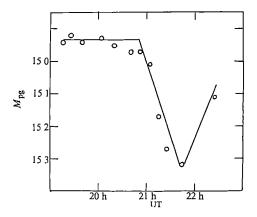
or approximately 5 AU


Fig 1 Light curve of 3C271

Assuming that the velocity of these objects is less than the velocity of light, their dimensions could be in the range 10^{12}–10^{13} cm, with a volume of 10^{36}–10^{39} cm^3

Setting a typical mass as 5×10^{10} $M_\odot$ their density will be some 10^5–10^8 g cm^{-3}

Such objects may resemble the hyperdense bodies required by Ambartsumian's theory[3] that galaxies and stars arise as a result of disintegration of compact objects

Galactic gamma rays from the superposition of X-ray sources

SATELLITE observations[1-3] show an enhanced flux of high energy photons (>30 MeV) along the galactic plane The intensity has a broad and flat maximum extended $\sim$ 60° around the galactic centre The average value of the flux in the central region is $(1 1 \pm 0 3) \times 10^{-4}$ photons (cm^2 sr)$^{-1}$ in the anticentre direction it is about a factor of five less The energy spectrum in the range (35–210)MeV is quite flat and possibly indicates that the gamma rays arise from decay of π^0 mesons

Various models have been proposed to account for this flux in terms of collisions between cosmic rays and interstellar matter On these models the observations of gamma rays would give important indication on the distribution of matter and cosmic rays[4,5]

The distribution of gamma rays also resembles the distribution of X-ray sources inferred from the third Uhuru (3U) Catalog So the gamma-ray flux may result from the superposition of sources rather than having a diffuse origin This idea is not new[6-8] but the better quality of SAS-II observations compared with those of OSO-III and the larger extent 3U encouraged me to reconsider the problem

Figure 1 shows the distribution of the counts from galactic compact X-ray sources and that of gamma rays observed by SAS-II and OSO-III The distribution of the X-ray counts has been obtained by unfolding that relative to 3U sources with the same angular response function of SAS-II ($|b^{II}| < 10°$) in the regions $180° < l^{II} < 50°$, $160° < l^{II} < 180°$, and with the one of OSO-III ($|b^{II}| < 15°$) in the region $50° < l^{II} < 160°$ For variable sources I have assumed the

minimum flux (this is justified because of the small duty cycle of the flare activity) The width of the central maximum of the X-ray counts distribution is of the same order of magnitude as that reported by SAS-II for gamma rays The flux of galactic gamma rays shows secondary peaks corresponding to regions where the X-ray sources are very powerful or very numerous Nevertheless, this fit is inadequate because the ratios of the values of counts at various galactic longitude are very different for the gamma and X-ray distributions A good agreement is obtained by considering only the steady sources (Fig 2) This distribution does not take into account the sources 3U0620+23 and 3U1510-59 (possibly supernova remnants) and the anomalously strong (variable ?) sources 3U1636-53 (261±3 counts s^{-1}) and 3U1735-44 (210±6 counts s^{-1}) The source 3U1728-24 has also been excluded because it seems to be variable[8]

The dashed line shows the gamma-ray distribution The best agreement between the two distributions is obtained if one assumes that the sources emit equal amounts of energy in the X and gamma range This requires the spectrum of the sources to be very hard (a hard spectrum is consistent with an extrapolation[10] up to energy of 100 MeV of the gamma-ray emission data from Cyg X-2 in the range 1-10 MeV) or that there is an additional mechanism leading to gamma-ray emission At present the models proposed for the X-ray emission suggest thermal sources with a temperature $kT \leqslant 100$ MeV But flare-like emission at this energy could occur in the presence of strong magnetic fields with a particular configuration of the force lines In this case protons could be accelerated to energies so high as to produce, in p-p collisions, neutral mesons which in turn decay in two gamma rays

Fig. 2 ——, Distribution of counts from steady X-ray sources, – – –, distribution of gamma rays

In my opinion it is, however, premature to conclude that the gamma-ray flux observed by SAS-II and OSO-III is the result of a superposition of sources rather than to cosmic ray collisions Indeed, if X-ray sources are distributed along the spiral arms, their gamma-ray flux would have the same geometry as that resulting from cosmic ray collisions

The model could be tested by searching for time variations in the gamma-ray counts (one can reasonably expect them if gamma rays arise from flares) and by obtaining gamma-ray data with better angular resolution to bring into evidence peaks in correspondence to individual X-ray sources

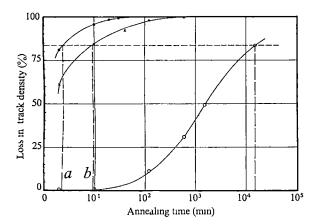
'Seasoning' of latent damage trails in lunar samples


CHARGED particle track analysis has been used extensively in the study of both terrestrial and lunar samples[1-5] In the latter, the tracks are produced by both internal and external sources A careful analysis of etched track parameters not only helps in identifying various track-producing sources but also yields useful information about their charge and energy spectra Most of the lunar samples analysed[6] show that the track parameters of iron group nuclei from solar and galactic sources are very different from and more stable than those produced by (for example) 9 6 MeV per nucleon ^{56}Fe ions in simulation experiments in the laboratory Similar effects are expected for other charged particle tracks It seems as though the latent damage trails in lunar samples have been 'seasoned' or their structures have been so modified by lunar conditions (particularly, lunar temperature and high doses of light charged particles) that significant changes are brought about in their properties

Thus, to interpret correctly the results of charged particle track analysis of lunar samples, one needs to study the

characteristic differences between naturally 'seasoned' tracks in lunar samples and 'unseasoned' tracks produced in the laboratory Here we describe a study of the relative roles of temperature and time in the process of 'seasoning' Attempts have been made to 'season' or to 'stabilise' the latent damage trails by annealing the samples under various combinations of temperatures and time intervals We also give a comparison of the annealing properties of 'seasoned' and 'unseasoned' damage trails

A big piece of tektite glass was exposed to thermal neutrons to produce induced fission of uranium atoms present in it as an impurity The piece was then cut into a number of slices On polishing and etching the slices, they were found to have a track density of about 10^6 tracks cm^{-2} The uranium distribution in the glass was extremely uniform The slices were then broken further into small parts, and some of them systematically annealed at temperatures of 300 °C, 500 °C and 550 °C for time intervals varying from 2 min to $1\,6 \times 10^4$ min, 6×10^2 min and 3×10^1 min respectively The purpose of these investigations was to study the track annealing properties of the glass and the characteristic differences between 'long term' and 'short term' annealings The slices annealed at 300 °C for $1\,6 \times 10^4$ min simulate the production of the 'seasoned' or 'stabilised' tracks, those annealed at 500 °C and 550 °C for 600 and 30 min respectively produce 'unseasoned' tracks The loss in track density (expressed as a percentage of the unannealed track density) is given as a function of the annealing time in Fig 1 To produce the same degree of annealing in samples exposed to different temperatures, they were to be annealed for such times that equal losses in track densities were obtained for all the samples Figure 1 shows that to have a loss in track density of (say) 84% for the samples annealed at 550 °C, 500 °C and 300 °C, we need annealing times of 2 3, 9 3 and $1\,6 \times 10^4$ min respectively In practice, the sample annealed at 300 °C for $1\,6 \times 10^4$ min (sample A) was kept for further experiments, while two new samples (B and C) were annealed afresh at this stage Thus all the three samples contained fission tracks annealed to the same degree but in different modes sample A contained 'seasoned' tracks while B and C contained 'unseasoned' tracks All the three samples were annealed later at 300 °C for time intervals ranging from 2 min to $1\,6 \times 10^4$ min, and the loss in track density as a fraction of the 16% tracks surviving after the first annealing step (Fig 1) was plotted as a function of annealing time (Fig 2) Although there is no appreciable difference in the residual track densities for shorter annealing times ($\lesssim 10^2$ min), the longer annealing times do show a marked difference in the stabilities of 'seasoned' and 'unseasoned' tracks—the 'seasoned' ones being the more stable

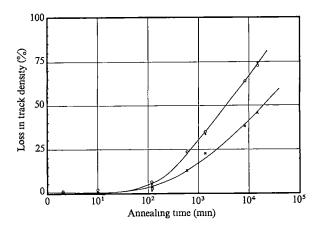
Fig 1 The annealing pattern of (neutron induced) 'fresh' fission tracks in a tektite glass as a function of the temperatures and time intervals used ●, 550 °C, ○, 300 °C, ×, 500 °C


Fig 2 The annealing behaviour of 'seasoned' and 'unseasoned' fission tracks in a tektite glass as a function of time at a fixed temperature of 300 °C 'Seasoned' tracks are more stable ●, 550 °C, ○, 500 °C, ×, 300 °C

So annealing temperatures and their duration are important for the redistribution of the damage pattern during the 'seasoning' process For example, a latent damage trail annealed at a low temperature for a long interval of time (conditions similar to lunar environment) readjusts itself to a more stable state than if it is subjected to a high temperature for a short interval of time Thus, the degree of annealing is not the only important parameter in controlling the redistribution of the damage pattern, but the 'mode of annealing' plays an equally important role This implies that the etched track parameters of 'seasoned latent damage trails' (as mostly found in lunar samples) and the 'unseasoned ones' (as obtained in the laboratory) will differ significantly Their direct comparison is not justified and more work is necessary on the two types of tracks before any firm conclusions may be drawn

Molecular stratigraphy

ORGANIC molecules contained in sediments were called 'chemical fossils' by Eglinton and Calvin[1], and Calvin[2] has used the term "molecular palaeontology" to emphasise the biological heritage of those components They recognised the important concept that molecular organic components in sediments may be viewed in much the same way as morphological remains of organisms Others have rigorously examined this concept and solidified its basis[3-6] We report organic geochemical data on some Pleistocene sediments, correlated by physical stratigraphic methods, which indicate

that the organic composition of sediments may be utilised as a correlation parameter comparable to morphological fossils in biostratigraphy The samples we have chosen for study are lacustrine sediments from two Pleistocene basins of eastern California

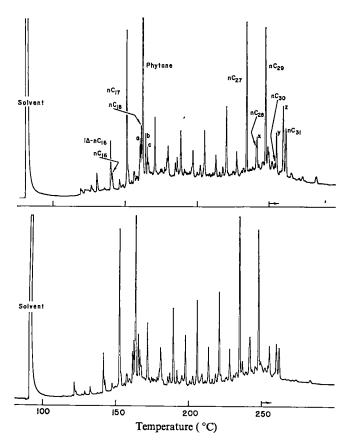
Mono and Searles Lakes are two of several strongly alkaline desert lakes of eastern California Mono Lake is in a closed drainage basin, with neither an outlet to the sea nor a sink The lake is now desiccating[7-10], although it is not yet sufficiently concentrated to deposit salts Mono Basin contains a sequence of Pleistocene lacustrine silts and diatomites approximately 1 5 km thick[8,11] Arching of the


Fig 1 Gas chromatograms (nC$_7$ fr) of time equivalent sediment samples, Mono Basin, California The two samples were collected from measured stratigraphic sections located 2 4 km apart (Analysis was on a 15 m×0 5 mm support coated open tubular column, coated with SE-30, helium carrier gas flow 4 6 ml min^{-1}, temperature programmed 80–250 °C at 2 °C min^{-1}, injector temperature 275 °C, detector temperature 295 °C.)

bottom of the lake, forming Paoha and surrounding islands occurred late in the development of the basin[8][12] Detailed stratigraphic columns of Late Pleistocene sediments, given the informal designation Paoha Island Sequence, were measured on Paoha Island The sediments are generally finely-laminated algal silts, diatomaceous silts or silty diatomites, with some sands through the section, and rare basaltic and rhyolitic tuffs[13] The samples from Mono Basin were collected from measured stratigraphic sections 2 4 km apart Correlation of the two measured sections is based on lithologic sequences

Searles Lake is the dry vestige of one of a chain of four Pleistocene Lakes[14,15] Searles Basin contains a remarkable sequence of Pleistocene salts and muds, approximately 1 km thick[16], salts and brines from the basin are being mined on a large scale Kerr–McGee Chemical Corporation donated four core segments (cores B, C, D, E) of the Parting Mud[1] cores B and C were drilled 2 6 km apart, and cores D and E 3 4 km apart The sediments consist primarily of finely laminated clays, occasionally with intercalated thin lamina of various carbonate minerals The presence of aragonite dolomite, pirssonite and gaylussite has been documented by X-ray diffraction Large (>2 cm), apparently diagenetic crystals of pirssonite and gaylussite, oriented by their 'c axes at high angles to bedding, are common in parts of these cores We found no sand in the section studied Stratigraphic correlation between drill cores is based on thin (2–3 mm rhyolite tuffs, now largely zeolitised to phillipsite, which occur near the top of the Parting Mud

We used a mixture of benzene and methanol (3 1 v/v to extract the organic components from dried, powdered sediment samples The concentrated extract was fractionated by liquid–solid chromatography on silica gel, successively eluting with heptane, 5, 10, 15 and 20% (v/v) ethyl acetate in heptane, ethyl acetate and methanol The heptane eluate (nC$_7$ fr) was analysed by gas–liquid chromatography (GLC) After initial GLC analysis, the heptane eluate was segregated further into three component fractions using silver nitrate impregnated thin-layer chromatographic plate (silica gel G, 0 25 mm, 15% AgNO$_3$ in methanol, mobil phase heptane–benzene=99 1) After recovery each of these three fractions was again analysed by GLC, with authentic compounds coinjected The final analytical procedure was combined gas chromatography–mass spectrometry (GC–MS on a DuPont 21-491 mass spectrometer

For this work we have sampled time-equivalent strata at widely separated locations Mono Basin samples 1-L-76 and 1-L-76(10B) represent exact lateral equivalents, in the Searles Basin samples, Bed T2b (Core B) is the exact lateral equivalent of Bed C-6 (Core C), similarly Bed D-4 (Core D corresponds to Bed E-4 (Core E) The total proportion of extractable material in a sediment and the concentration of hydrocarbons in that extract has been used in the past to judge similar organic compositions[17] Our extraction data (Table 1) for precisely correlated beds within a sedimentary sequence indicate that this criterion may be uncertain

Stratigraphic variability in organic composition for sediments from Mono Basin has already been documented[13][18] Figure 1 shows that sediment samples of the same bed collected from localities 2 4 km apart, possess an identical distribution of individual molecular components Phytane (2,6,10,14 tetramethylhexadecane), nC$_{17}$, nC$_{27}$, and nC$_{29}$ are the dominant compounds in the hydrocarbon fraction of these samples The homologous series of n-alkanes has an attendant homologous series of mono-olefins, one of which is labelled (1Δ-nC$_{16}$) on the figure Peak a represents a composite of two components, one an unidentified branched alkane, the other being 1Δ-nC$_{18}$ Identification of peaks b c, x, y, z is still unsubstantiated

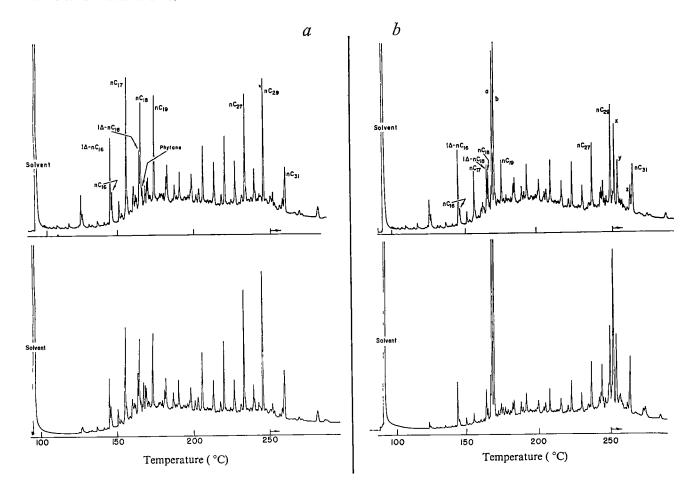
Figure 2 also illustrates lateral continuity in organic composition, although two stratigraphic horizons in Searles Basin have different compositions, each unit laterally ex


Fig 2   Gas chromatograms (nC_7 fr) of time equivalent sediment samples, Searles Basin, California Analytical conditions as for Fig 1
a, Bed T2b (core B) is the exact time equivalent of Bed C-6 (core C), the core locations are 2 6 km apart These samples represent
the interval 1–4 mm below Tuff II *b*, Bed D-4 (core D) is the time equivalent of Bed E-4 (core E), the core locations are 3 4 km apart These
samples represent the interval 778–790 mm above Tuff I

hibits a consistent composition The series of mono-olefins observed in the previously discussed samples is more prominent in these sediments from Searles Basin For the stratum correlated between cores D and E, the two most abundant constituents (Fig 2*b*, peaks a and b) are mono-olefinic *iso*prenoids (peak a   3,7,11,15 tetramethylhexadec-1-ene, peak b   3,7,11,15 tetramethylhexadec-2-ene) The mass spectra for these two components were identical, assignment of the double bond position is based on GLC retention times[19] Identification of peaks x, y, and z is still unsubstantiated, peak x seems to represent a mixture of two $C_{28}H_{46}$ sterenes, and peak z a mixture of two $C_{30}H_{50}$ pentacyclic triterpenes

Therefore we agree with Eglinton and Calvin[1,2] on the fossil nature of some organic molecules in sediments We suggest the new term 'molecular-stratigraphy', to convey the qualification that not only are organic molecules inherited from biota, but that these molecules must be constrained by biostratigraphic principles such as facies Lateral variation in the molecular organic composition of a stratigraphic unit may result either from ecologically controlled distributions of biota, or from selective preservation (over- or under-representation of components depending on the character of the material being fossilised with respect to depositional regime) The lacustrine sediments we have examined in this study grade laterally into alluvial sedimentary sequences The organic composition of the alluvial facies no doubt will be different from that of the lacustrine facies In this work we selected time-equivalent samples

representative of the same depositional facies In sedimentary sequences where fossils are scarce, molecular stratigraphy may represent the only correlation parameter available

Electron spectroscopic observations on extreme pressure lubrication

COMPOUNDS of sulphur, phosphorus, zinc and chlorine are added to lubricating oils to control wear under arduous conditions by forming films on rubbing surfaces The films are extremely thin and frequently amorphous Only rarely has it been possible to identify compounds present although electron probe microanalysis can show the distribution of elements We here present new information, obtained from electron spectroscopic measurements, mainly concerning the binding energies of photoelectrons (ejected with $AlK\alpha$ X rays) the magnitudes of which are characteristic of particular atoms and electrons, and which may therefore be used for analytical purposes We also made some observations of the kinetic energies of Auger electrons, which are also well defined and of analytical value These energies depend on the charge on the atom, so that for states of combination of an element where the charges on the atoms are sufficiently different, valuable 'chemical shifts' are observed, sulphur is a favourable case with a shift of about 6 eV from sulphide to sulphate Only electrons that escape without collision are of value, so the analysed depth was limited to a few tens of Å, the region of interest in lubrication

Specimens of EN31 steel, after diamond polishing and scrupulous solvent cleansing, were treated in solutions of additives in non-polar white oil They were either statically immersed for 16 h at a temperature of 145 °C, or rubbed for 10 min against a disk of the same material in a wear machine Before examination in the electron spectrometer the specimens were washed in non-polar solvents to remove oil

The surface of a specimen immersed in a solution of elemental sulphur in white oil showed S2p peaks, denoting binding energies of 168 8 and 164 eV The first peak value was greatly diminished by washing the specimen in water, it matched that of a thin layer of sulphate on iron The second value was reasonably close to that obtained for elemental sulphur The peak value was not, however, much reduced by washing in carbon disulphide, so reservations must be made in attributing it to sulphur The rubbed specimen showed much less sulphate but gave a large signal corresponding to sulphide, and part of the surface oxygen was seen from the oxygen 1s spectrum to correspond to oxide We conclude that whereas the specimen which had been immersed had a rather uniform coating of iron sulphate, the surface of the rubbed specimen was at least partially oxidised and carried a relatively thick but discontinuous layer of iron sulphide

A specimen heated in a solution of dibenzyl disulphide in white oil gave peaks in the same positions as the sulphur solution Again, that which indicated a binding energy close to 169 eV was very sensitive to washing in water, and we therefore attributed it to sulphate The interpretation of that at approximately 164 eV is less straightforward in that the additive itself gave a very similar binding energy We found, however, that dibenzyl disulphide could be removed by the solvent washing It was also sensitive to washing in water unlike the substance on the specimens The peak at 164 eV cannot, therefore, be attributed to dibenzyl disulphide Dibenzyl monosulphide, a proposed intermediate[1-2] which has a closely similar binding energy, can be ruled out because it volatilises in the vacuum of the spectrometer Benzyl mercaptide can also be ruled out because it would give a peak in the ferrous sulphide position As in the previous experiment, it is tempting to assign this peak to sulphur, but there must be reservations

The specimen rubbed in the white oil solution of di-benzyl disulphide also behaved very like that in the sulphur experiment, showing mainly sulphide sulphur, with some sulphate, and oxygen present in part as oxide

Most of our work has, however, been done with a commercial zinc dialkyldithiophosphate additive in which the alkyl groups .are predominantly methylpentyl This additive contains 13% mineral oil Pure zinc di-n butyldithiophosphate was also examined

Specimens immersed in solutions of the commercial additive in white oil had zinc, phosphorus and sulphur on the surface, the sulphur was in two forms, the more abundant of which corresponded to sulphate The zinc phosphorus and the minor sulphur component displayed electron binding energies indistinguishable from those of the original additive The binding energy of that sulphur was also the same as that of sulphide sulphur Electron spectroscopy alone, therefore, could not distinguish between the two possibilities that the minor sulphur was present as a sulphide film or was present together with the zinc and phosphorus in a layer of adsorbed additive The second possibility was eliminated by re-examining the specimens after they had been washed in boiling acetone This treatment, which supposedly[3] removed adsorbed additive, did not change the spectrum Although the possibility that a sulphide film is present is not completely out of the question it seems more likely that the minor sulphur is bound up, together with the zinc and phosphorus, in a decomposition product of the original additive The evidence for this is the relatively small variation of the atomic ratios of zinc phosphorus sulphur found in our experiments over a range of conditions This ratio is, for example, 1 1 0 6 at 140 °C, whereas that for the original additive is 1 2 4 Zinc phosphate, zinc sulphide and zinc sulphate were not present and the presence of zinc oxide also seems unlikely from a consideration of Auger line widths These observations, together with others not reported here, suggest that the reaction mechanism varies with temperature and that a complex, possibly polymeric, phosphate forms on the metal surface on which there is also iron oxide and possibly iron sulphide or sulphate The pure di-n-butyl compound gave much less sulphate on the surface, which suggests that in the commercial additive either impurities which contained sulphur or sulphur contained in the mineral oil carrier contributed largely to sulphate formation

As with the sulphur additives, the specimens rubbed in the solution of the commercial zinc dialkyldithiophosphate showed a much smaller sulphate peak, but otherwise the spectra were rather similar to those of the immersion specimens The atomic ratios of zinc, phosphorus and sulphur showed less variation and more of the surface was iron oxide

Other investigators have suggested that it is possible, under various conditions and at various temperatures, that adsorbed additive iron sulphide and iron benzyl mercaptide are responsible for the anti-wear performance of the dibenzyl disulphide (refs 1 and 2, and R C Coy and T F J Quinn, unpublished) The literature on zinc dialkyldithiophosphates proposes many reaction schemes, often unsupported by analytical evidence, in which zinc oxide, zinc sulphate, zinc phosphate and polymers with definite zinc–phosphorus–sulphur ratios of 1 2 4 to 1 2 2 are postulated (see refs 3–5)

The methods of electron spectroscopy clearly provide new opportunities for progress in the study of lubrication phenomena In particular, they have given information on very thin films on rubbed surfaces—films which have been too thin to examine by other means Additionally, by showing large differences in the compositions of films on immersed and rubbed specimens, they indicate the dangers inherent in basing reaction mechanisms on immersion tests alone

A fuller account of this work will be published elsewhere

table cold cathode arc

HE cold cathode arc, so called because of the very high current ınsities and low temperatures observed at the cathode, has ıen subjected to ıntensıve theoretical and experımental study[1-4] Iany theories of the 'cathode spot' have been proposed, but ıstınguıshıng between them experımentally has proved to ɛ a formıdable task, because of the rapıd and unstable motıon f the spot, and the large pressure and temperature gradients ıstıng wıthın a very short dıstance of the cathode surface

It is possible that a caesıum discharge run at temperatures ɔ to 1,200 K wıth a tungsten cathode, and with the entıre .scharge (not just the electrodes) heated externally, may ɛhave as a stable, cold cathode arc The low ıonısatıon otentıal of caesıum (3 9 V) could allow enough plasma by ıermal ıonısatıon for measurable currents to be obtaıned, nd the work functıon of tungsten (4 5 eV) may be hıgh enough ɔr cold cathode behaviour to occur

The discharge tube consısted of a commercıal, hıgh pressure, ɔdıum arc lamp, wıth the arc tube fılled wıth 0 1 g of caesıum ıstead of sodıum The arc tube was made of 8 mm diameter lumına, wıth a space of 9 cm between tungsten electrodes f 1 cm² surface area There was a sılıca-glass outer tube, nd the space between the tubes was fılled wıth argon at a ressure of 200 mm Hg The device was enclosed ın a cylındrıcal ırnace capable of producıng temperatures of up to 1,400 K, ıth an adjustable temperature control, and wıth ıts axıs ıclıned at about 20° to the horızontal Tungsten wıres to the lectrodes of the device were brought out of the furnace ın ın, sealed, sılıca-glass tubes Temperatures of up to 1,100 K ıere achıeved wıthout damage

Before measurements were taken, the posıtıon of the arc ıbe relatıve to the temperature gradient along the furnace ıigher temperature at the hıgh end) was adjusted untıl lıquıd aesıum was observed to condense only at the colder end of he arc tube The temperature of the caesıum gas was taken ɔ be that measured by a thermocouple near the hotter end ıf the tube The temperature of the caesıum lıquıd (whıch ontrolled the gas pressure) was estımated to be 5% lower Kelvın) than the gas temperature, whıch corresponded wıth he temperature measured by a thermocouple near the colder nd of the tube

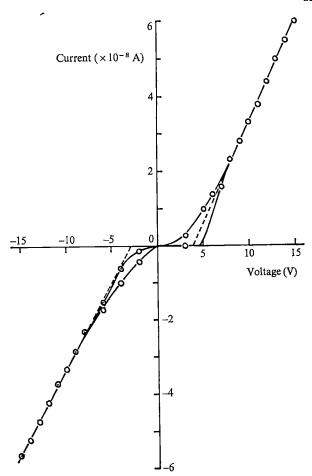
A typıcal plot of current agaınst voltage (Fıg 1) shows that or both current dırectıons, there ıs a proportıonal ıncrease ıf current above about 8 V, indıcatıng a constant electrode ɔltage, and a constant arc column resistance The slope of he straıght lıne (Fıg 1) gıves the resistance of the column, ınd ıts ıntercept on the voltage axıs gıves a measure of the lectrode voltage The electrode voltages obtaıned when the ɔlder electrode was used as cathode were discarded, as they ended to vary (presumably dependıng on the amount of ontact between the tungsten electrode and the lıquıd caesıum) The electrode voltages obtaıned when the hotter electrode was ,sed as cathode, however, were relıable and repeatable and he shapes of the curves on ınıtıal applıcatıon of voltage


Fig. 1 Typıcal plot of current agaınst voltage Gas temperature, 760 K Posıtıve readıngs for hotter electrode as cathode

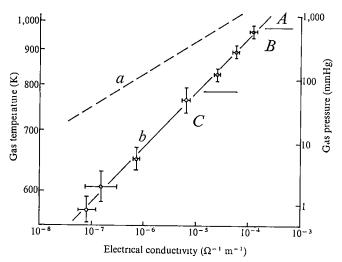
(Fıg 1, the lower curve) and on subsequent applıcatıons (Fıg 1, the upper curve), seemed to rule out thermıonıc emıssıon

The electrical conductıvıty, σ, of the caesıum column was derıved from the resistance measurements Log σ was then plotted agaınst the recıprocal of the gas temperature, T, the result was a straıght lıne (Fıg 2) The electrode voltage ob-taıned when the hotter electrode was used as cathode was also plotted agaınst $1/T$ (see Fıg 3) It was found that the experı-mental poınts could be fitted to an exponentıal curve (Fıg 3) with an asymptote at 2 65 V

Above a gas temperature of about 970 K (~1 atm gas pressure), no arc could be obtaıned, and the current dropped below the measurıng lımıt of the apparatus ($<10^{-10}$ A) Be-tween about 770 and 970 K, the arc could be made to run, and when ıt did run ıt gave repeatable results, but ıt showed a tendency to extınguish or not to start at all Below about 770 K the arc would always run

The standard formula for the electrical conductıvıty of a weakly ıonısed gas ıs $ne^2/n_a mcq$, where n ıs the plasma number densıty, n_a the gas number densıty, and e, m, c and q, respec-tıvely, the electron charge, mass, thermal speed, and collısıon cross sectıon for momentum transfer wıth neutral partıcles Assumıng thermodynamıc equılıbrıum condıtıons, Saha's equatıon may be applıed[2] to yield $n^2 \alpha n_a \exp(-e\bar{V_i}/KT)$, where $\bar{V_i}$ ıs the effectıve ıonısatıon potentıal, and the dependence of the constant of proportıonalıty on temperature can usually be neglected ın comparıson wıth the rapıd varıatıon of the ex-ponentıal term wıth temperature Thus, the electrical conduc-tıvıty should obey a relationshıp of the form

$$\sigma = \sigma_0 \exp[-e(\bar{V_i} - V_{evap})/2KT]$$

where $n_a \alpha \exp(-eV_{evap}/KT)$ ıs used, wıth V_{evap} ıncreased by


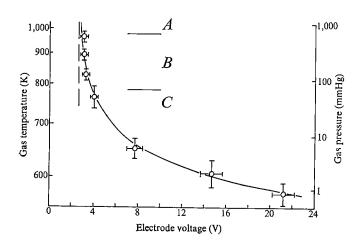


Fig 2 Relationship between gas temperature and pressure and electrical conductivity *a*, Theoretical line assuming no wall/electrode excitation mechanism *b*, experimental line *A*, region of no arc, *B*, region of marginally stable arc, *C*, region of stable arc

5% from its standard value, to allow for the fact that the caesium liquid temperature is 5% below the gas temperature

The dashed line in Fig 2(*a*) is obtained by substituting $\bar{V}_i = V_i = 3\,9\,V$ and $q = 1\,5 \times 10^{-14}\,cm^2$ into the formula for σ Clearly, straightforward volume ionisation is not the dominant mechanism The experimental line (Fig 2*b*) corresponds to $\bar{V}_i = 2\,64\,V$ and $q = 4\,10^{-12}\,cm^2$, with estimated errors of $\pm 0\,2\,V$ on $\bar{V}_i$ and up to a factor of 3 on q This result is readily interpreted in terms of a dominant mechanism involving excitation at the walls or the electrodes of the discharge The lowest excitation potential of caesium, V_{exc}, is $1\,4\,V$, so that the voltage required to ionise excited atoms is $(V_i - V_{exc}) = 2\,5\,V$, agreeing with the measured $\bar{V}_i$ within the experimental accuracy In fact, at these temperatures, a very long time is required[2] to achieve volume thermal ionisation, so any appreciable wall or electrode mechanism could be expected to dominate Furthermore, the very large experimental cross section (even allowing for the large possible error and the fact that the gas is caesium) provides a strong indication that the neutral particles are likely to be excited atoms or molecules

Fig 3 Relationship between gas temperature and pressure and electrode voltage Experimental points are for the hotter electrode as cathode The smooth curve is an exponential curve fitted to the experimental points, with asymptote at 2 65 V Regions *A*–*C* as for Fig 2

The asymptotic value of electrode voltage, 2 65 V (Fig 3) is also consistent with an explanation in terms excited atoms Allowing for a small drop in anode volt $(\sim KT/e)$, the asymptotic cathode voltage is again very cl to $(V_i - V_{exc})$ Robson and von Engel[5] have proposed a mech ism which seems to account for these observations Exc atoms impinging on the cathode release secondary electr with a high yield The net energy required for an electron escape is $e(V_i - V_{exc})$, and this determines the cathode volt required

The exponential curve fitted to the electrode voltage readi in Fig 3 may be expressed in terms of gas number densit

$$V = 2\,65\,[1 + (n_0/n_a)^{2/3}]$$

where $n_0 = 4 \times 10^{17}\,cm^{-3}$ In terms of the interparticle sep tion distance for neutrals $\lambda_a = n_a^{-1/3}$, this becomes

$$V = 2\,65\,[1 + (\lambda_a/\lambda_0)^2]$$

where $\lambda_0 = 1\,4 \times 10^{-6}\,cm$ Now λ_0 is about twice the s length for the Schottky inverse square law image force act on electrons associated with the surface potential barr Thus, the experimental result implies that when the neu interparticle separation distance increases to a value compara to the range of the surface potential barrier, more cath voltage is required to pull electrons clear of the surface T again is entirely consistent with the Robson–von En explanation

What is the reason for the arc failing to run above 970 One possibility is that volume ionisation and thus (by principle of detailed balancing) volume recombination beco more important than surface effects above this temperatu and the discharge reverts to full volume equilibrium But dashed line in Fig 1 suggests that even if that were to oc there should still be an easily measurable current It would a be necessary for a volume mechanism for quenching exci states to become important[2] That would suppress the emissi process suggested by Robson and von Engel and the curr would then drop to the thermionic emission level for tungst below the minimum that could be detected

Finally, a 'unipolar' arc effect was also observed Wh the arc was run for long periods (30 min or so) in one directi it could be observed to charge up, just like a battery It wo then deliver current to a resistive load for a comparable peri The 'e m f' associated with the effect was about 1 8 V T may have been caused by a monolayer of caesium ions hering to the tungsten electrode, as has been observed Langmuir and coworkers[6] at much lower pressure, but if then it must have been formed at the anode during the chargi process, and not at the cathode If it had been formed at t cathode, it would have caused current to continue in the sai direction after removal of the supply voltage, contrary what was, in fact, observed

I thank F J L Crammond and his colleagues at Tho Lighting, Leicester, for invaluable assistance with a diffici apparatus, and J E Allen for helpful discussions which l me to try this experiment

Electromagnetic effects at metallic fracture

JUST at the instant of tensile fracture of low-carbon iron specimens a transient magnetic field of the 'order of 1,000 gauss is produced[1]. This phenomenon is observed even in the absence of any external magnetic field. Only the surface region of the fractured pieces are magnetised, with the fractured ends exhibiting distinct and opposite polarities. The magnetisation of each piece varies along the length, with maximum at the fractured end. Moreover, the induced magnetisation is retained for about 15 d in larger specimens and then decays almost exponentially. Iron specimens fractured under impact forces did not show any magnetisation. I now report observations of the complementary phenomenon of generation of an electric field at the instant of tensile fracture of metallic specimens, ferromagnetic as well as non-ferromagnetic.

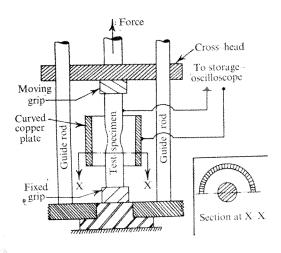
Metals investigated, were 0.15% carbon steel, aluminium (4.5% Si, 0.5% Fe, 95% Al), brass (63.5% Cu, 0.1% Pb, rest Zn), zinc (99.67% pure) and lead (99.43% pure). The ultimate tensile strengths of these materials were of the order of 39.0, 29.4, 33.2, 6.2 and 2.0 kg mm^{-2}, respectively. The zinc and lead rods were processed by metal mould casting and the others by hot rolling.


Fig. 1 Schematic diagram of the force application system of the tensile testing machine.

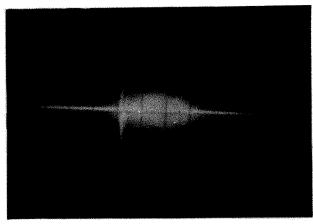
External electrical and magnetic disturbances (including the Earth's field) were shielded out during the experiments. Test specimens were stressed in vertical and horizontal directions, and also in different orientations with respect to the magnetic meridian. A coaxial, semicylindrically curved copper plate (30 mm internal diameter and 50 mm long) was used as an electric field sensor. A Hewlett Packard variable persistent storage oscilloscope was used to record the phenomenon. Measurements of potential difference were also made with the help of a d.c. microvoltmeter. The potential pickup wire soldered on to the outer surface of the curved copper plate was connected to the storage oscilloscope and the ground wire, first direct on to the surface of the test specimen with the machine body grounded separately and then with the ground wire of the oscilloscope connected to the machine body without disturbing the test specimen, the latter being at ground potential by contact with the machine parts. The curved copper plate did not suffer any mechanical jerk resulting from stressing and fracture (Fig. 1).

Test specimens had dimensions 9 mm diameter × 160 mm long and were fractured under tension in a horizontal Housfield Tensometer. The test specimens were machine turned to a


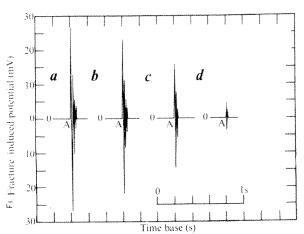


Fig. 2 Photograph of the voltage against time plot obtained on the storage oscilloscope for an aluminium specimen.

diameter of 7 mm in the central zone (Fig. 1) to ensure fracture in the centre. The transient magnetic fields in ferromagnetic specimens at the instant of tensile fracture were measured simultaneously as in my earlier work[1]; the results agree with those of that study.

Figure 2 is a photograph of the voltage time plot obtained on the oscilloscope during the tensile stressing of an aluminium specimen. It shows the generation of an electric field just at the instant of fracture. The voltage developed seems to be oscillatory in nature, marked by rapid damping. The diffused light in the vicinity of the horizontal time axis in the photograph is caused by the trace-blooming effects of the oscilloscope beam because of its excessive intensity. Similar curves were obtained for all metallic specimens (steel, aluminium, brass and zinc) but the amplitudes of the voltage generated were different for different materials. Figure 3 shows the tracings of the curves obtained on the storage oscilloscope for different materials, both qualitatively and quantitatively. The nature of the curve is independent of the orientation of the specimen. Expanding the time scale on the oscilloscope was not achieved because of the difficulty of synchronisation of the oscilloscope triggering to the instant of fracture. An expanded time scale would probably have exhibited the phenomenon more clearly.

Results with lead rods were of particular interest. Rapid fluctuations of electrical potential difference of the order of ±40 μV (peak value) ocurred as soon as the cross-sectional area of the lead specimen started reducing rapidly, instead of a first sharp peak value at the instant of fracture as in other cases. This may be because lead is very soft, plastic in nature and

Fig. 3 Tracings of plots obtained for: *a*, carbon steel; *b*, aluminium; *c*, brass; *d*, zinc. A, Denotes instant of fracture.

under uniaxial tension it suffers a rapid decrease in cross-sectional area leading to a point fracture. Moreover, the number of current carriers per atom based on a free electron model for lead is very high[2].

The twin phenomena of the generation of electric and magnetic fields at the instant of tensile fracture basically represent the electromagnetic effects of mechanical force fields in metals. Influencing parameters are likely to include: breaking stress, number and nature of current carriers per atom, electrical and magnetic structures of molecules of metals, mode of fracture, and crystal lattice structure. Furthermore, fracture phenomena are predominantly influenced by dislocations in dynamic state and energised shock waves. The observed electric and magnetic effects might be attributed to electron-dispersion analogous to the radiation of sound by dispersion of elastic vibrations of the crystal lattice as a result of dislocations[3].

A new approach to improvement of yam *Dioscorea rotundata*

Efforts to improve the yam, *D. rotundata*, through hybridisation have been frustrated by the low rate of flowering, the very low rate of fruit setting and poor seed germination[1-3]. These constraints have confined the availability of genetic resources for selection to the small number of cultivars which have been vegetatively reproduced from time immemorial. This continued vegetative propagation and the lack of hybridisation have precluded the possibility of introduction of new genetic characteristics, resulting in a stagnation of yam improvement. To facilitate yam hybridisation, we have re-examined the problems of flowering and seed germination. We first reported[4] yam seed germination in November 1973, and Doku stated

that he had germinated yam seeds of *D. rotundata* (unpublished) Here we report the feasibility of germinating yam seeds, the rapid improvement of flowering, and the opportunity this development affords for expanding present germ plasm collections, thus facilitating yam improvement.

After a series of unsuccessful attempts, we obtained good germination in early 1973 when two important limitations for seed germination became evident[5]. First, the majority of the seeds were found to lack embryos or endosperms and second, they were found to possess a dormancy period of about 3 months after harvest. Having discovered these two limitations seeds that seemed to contain embryos were selected and stored at room temperature until the end of the dormancy period. Seeds were sown in Petri dishes in March 1973, and in about 3 weeks more than 50% of the seeds germinated. After germination and the appearance of the first leaf, some 600 seedlings were transplanted into small pots and a month later, were transferred to larger pots and grown in the greenhouse. Tuber formation began about a month after transplanting. Flowering of some plants began in July 1973 with all the flowering plants bearing staminate flowers. None of the plants had produced any pistillate flowers by plant maturity. The plants showed a great deal of variability with respect to leaf shape, size and colour, canopy structure, stem colour and shape, plant height, and tuber shape and size. Tubers were forced to maturity by gradual decrease in watering and were harvested in February and March 1974, at which time most of the tubers weighed more than 500 g, which contrasts markedly with the observation of Waitt[2], whose material took 2 yr to produce a 450 g tuber from seed.

On April 1, 1974, each tuber was divided into several 'seed' (vegetative) pieces and planted in the field. The purpose of this second planting was to facilitate maximum growth, flowering and fruiting under field conditions and to provide at maturity, seeds to produce plants of a second generation in 1975. Throughout the growing season, data were collected on all phases of plant growth characteristics with special attention to date and degree of flowering and plant sex. Male plants began to flower in early July while female plants began to flower in late July and early August.

It was observed that the percentage of flowering plants, particularly females, was greater in the population originating from seeds than in those originating from tuber cuttings obtained by continuous vegetative propagation (Table 1). The degree of flowering per plant had also increased. Whereas plants grown from tuber cuttings usually produce less than 200 pistillate flowers per plant, plants originating from seed produced from 500 to 11,000 pistillate flowers. Furthermore,

Table 1 Comparison of the degree of flowering and plant sex between plants of *D. rotundata* originated from continuous vegetative propagation and from seeds

	Flowering (%)	Non-flowering (%)	Flowering plants (%)		
			Male	Female	Monoecious

Fig. 1 Degree of yam flowering and fruit set. *a*, Male plant; *b*, female plant at the fruiting stage.

4.7% of the plants derived from seeds, produced both staminate and pistillate flowers on the same plant (monoecious), which is an important departure from the usual production of either staminate or pistillate flowers on separate plants (Table 1). This quantitative and qualitative change in the flowering habit of plants of the first generation presumably resulted from our conscious selection for flowering through propagating plants from seeds. Since the low degree of flowering has been one of the major limiting factors in seed production, it is expected that after several generations the degree of flowering will increase to an extent such that it should be feasible to produce enough seeds to make yam propagation through seed a reality on a commercial basis. The increase in flowering and fruiting of plants produced from seed, did not reduce tuber yield. Tubers of up to 9 kg per plant were produced by plants from seed. It was notable that non-flowering plants yielded less than flowering plants and pistillate lines yielded more than staminate lines, thus suggesting that attention should be given to the former in selecting for high yields.

In a continued effort to increase our germ plasm collection by propagating plants from seeds, mature yam fruits were collected in October and November 1973 from eight sources in Nigeria. The seeds were germinated at the termination of the dormancy period as described earlier and the established seedlings were planted directly in the field. Seedling survival in the field was about 95% (Table 2), thus establishing the feasibility of planting yam seedlings directly in the field without the need for a pre-growth period in the greenhouse. Tremendous morphological differences exist between plants with regard to their canopy structure, leaf shape and size, climbing habit, stem colour and thorniness, date of flowering and abundance of flowers.

This study clearly demonstrates the feasibility of yam seed germination on a large scale and the possibility of greatly increasing the potential for improving genetical diversity and breeding resources. Whereas breeders have hitherto been limited in their selection schemes to the narrow genetic base in cultivars that have been under continuous vegetative propagation, it is now possible to select for desirable characters from almost unlimited numbers of new lines.

Spawning pheromone in crown-of-thorns starfish

LARGE aggregations of the crown-of-thorns starfish *Acanthaster planci* L have destroyed a high proportion of the coral on certain Indo-Pacific reefs. We report that gamete release by one *A. planci* induces other ripe starfish to spawn; similar behaviour has been observed in certain other echinoderms[1,2]. During natural spawning a pheromone is released from the gonad, which synchronises spawning in neighbouring animals and also induces starfish movement towards the spawning individual. Using a Y maze to study chemoattraction in spawning starfish, we have attempted to isolate and characterise the active gonad component.

Several starfish (between 8 and 15) were maintained in a large Y-shaped tank which allowed an equal water flow through each of the two arms towards the base. *A. planci* normally avoids light and during the day remains in a covered area at the base, only moving into the uncovered arms at night. On six occasions, however, a single starfish became active during the mid-afternoon, and subsequently spawned, after which the remaining starfish emerged and several spawned (15 animals in 34 trials). Out of the 34 trials, 29 starfish moved towards the arm containing the spawning animal and five towards the control arm ($\chi^2 = 15.4; P < 0.001$).

When a starfish spawns in an aquarium, other starfish in the same tank or in tanks on the same filtration circuit, also frequently spawn; those that do not may, however, show behaviour typical of spawning. Spawning behaviour may also occur in response to l-methyl adenine injected at too low a dose to cause spawning itself (C. Huxley, personal communication). This 'spawning behaviour' consists of rapid movement with all tube feet active, and with the starfish partially inverted at the water surface; it probably corresponds to the climbing behaviour observed in spawning *A. planci* in the wild[3,4]. Similar behaviour has been observed in *Crossaster* when spawning in aquaria[5]. Daytime movement and spawning behaviour are thus more consistent responses to a spawning stimulus than actual spawning, presumably related to the physiological limitation on frequent spawning.

Daytime movement could be induced by feeding stimuli such as coral extract; thus, although induction of movement provided

Table 1 Response of *A. planci* to chemical stimuli

Substance added	% Movement	% Spawning behaviour	% Spawning	No. of trials
None	11	1	1	206
Whole gonad	77	22.5	13	31
Sperm-free solution	100	100	0	2
Sperm	87	73	0	15
Retentate	30	15	0	6
Boiled fraction	40	10	10	10
Zeocarb (*p*H 7)	27	4	0	26
Zeocarb NH₃ fraction	51	13	13	15
GSS	0	0	0	6
Glycine 10⁻⁶M	0	0	0	7

Observations were made during the afternoon every 15–30 min for 1 h before addition of material to the tanks and 3–7 h thereafter. Forty starfish were available for assays, two to three to a tank (50 × 60 × 25 cm). Movement was recorded if an individual starfish moved during three successive observations; 'spawning behaviour' required a single observation during the experiment. The number of trials is the number of starfish assayed with each type of material. Figures indicate the percentage of starfish responding. Whole gonad extracts were prepared by distilled water lysis of male or female gonads treated previously with GSS. Sperm solutions were obtained from tanks in which starfish had spawned spontaneously. Retentate, material remaining in a dialysis bag after dialysis, against 3 × 2 l of distilled water, of filtered whole gonad extract (usually 200 ml). Boiled fractions are gonad preparations or sperm solutions boiled for 40 min. Dialysate of whole gonad extract was passed through a 10-ml column of Zeocarb 225 cation exchange resin at *p*H 7. The material which failed to attach to the column is 'Zeocarb *p*H 7', and that which was eluted with 1 M NH₃ is 'Zeocarb NH₃ fraction'. The gonad extracts were assayed at a concentration of the total gonad from 1 starfish per 50 l.

a convenient assay, a putative spawning factor cannot be judged on this criterion alone. The active component seems to be present in the gonad (Table 1) but not firmly attached to the gametes themselves; it is dialysable and heat-stable. Kanatani[6] reported that neither gamete-shedding substance (GSS) from radial nerves nor 1-methyl adenine act as pheromones in *Asterias amurensis*, although both are intimately involved in the internal control of spawning. We confirm that GSS has no effect when added to the aquarium, but the starfish could detect 1-methyl adenine at 10⁻⁸–10⁻⁹ M when applied externally. All eight starfish tested extended their previously retracted tube feet, but only one starfish showed full spawning behaviour. No response was obtained, however, at concentrations up to 10⁻⁷ M, although the spawning season had ended by this time. The role of 1-methyl adenine has yet to be confirmed.

Ovary and testis extracts (data not shown) are equally rich sources of active spawning factor and in contrast to certain echinoids[1], there seems to be no differential sensitivity between males and females. We have no evidence for a strict periodicity in the responsiveness to extracts; however, those animals which had spawned recently or tended to spawn most frequently in the aquarium were more responsive than those which spawned rarely or not at all.

Whereas gonad development seems to be largely controlled by seasonal factors, the triggering stimulus for spawning in an aggregated population may be the release of gametes by neighbouring starfish. Spawning can occur in isolated individuals (D.H.B., N.J.H., and R.F.G.O., unpublished) but probably results in negligible fertilisation. In the case of mini-aggregations[7], however, in which up to 15 starfish may be clustered around a single coral head (such as a large table of *Acropora*), a pheromone capable of attracting starfish over a distance of a few metres and also synchronising gamete release, would greatly increase the success of spawning. It has already been suggested[8] that a large increase in spawning efficiency caused by aggregation formation may contribute to the instability of *A. planci* numbers and the occurrence of periodic population explosions.

Production of verbenol pheromone by a bacterium isolated from bark beetles

THE aggregation pheromones of the bark beetle, *Ips paraconfusus* Lanier[1] are expelled in the faecal pellets of male beetles feeding on the phloem of *Pinus ponderosa*[2,3]. These substances, *cis*-verbenol, ipsenol, and ipsdienol[4], seem to originate in the hindgut[5] but the precise site of their biosynthesis has not been determined. In various species of *Ips* a connection has been convincingly demonstrated between the production of these pheromones in the hindgut and either ingestion of phloem or exposure of the beetles to host plant oleoresin[6]. More specifically, exposure of individuals of certain species of *Ips* to myrcene can result in an increased production of ipsenol and ipsdienol[7] and exposure of certain species of *Dendroctonus* to α–pinene results in an increased production of *cis*- and *trans*-verbenol[8–10] in the hindgut. It seems therefore that a precursor–product relationship exists between certain host plant substances such as α–pinene and myrcene and the three aggregation pheromones mentioned above.

A symbiotic relationship between an insect and a species of bacterium with respect to the production of the insect's sex pheromone, has been found in the New Zealand grass grub beetle[11] which carries a phenol-producing bacterium in the colleterial glands of the female. To our knowledge, however, the presence of microorganisms within the gut of an insect capable of transforming certain precursors to its pheromones has not been suggested.

Certain microorganisms can transform α–pinene into various substances including *cis*-verbenol and verbenone[12–15]. We therefore isolated a number of different microorganisms from the gut of adult male and female *I. paraconfusus* and determined their ability to transform α–pinene into *cis*- and *trans*-verbenol. All isolated species were grown aerobically in 100 ml of 3% yeast extract in a mineral salts medium[16] and shaken continuously. Good growth occurred in all cases within 24 h at which time 0.5 ml α–pinene was added and the flasks shaken for a further 24 h. Controls without either the microorganisms or α–pinene were run in the same manner. All flasks were extracted with ether, and, based on retention data of temperature-programmed gas chromatographic runs of the extracts (10% SP-1000, 60 °C to 200 °C at 10 °C min⁻¹), one organism in particular seemed to be producing the verbenols and this was identified as *Bacillus cereus*. This was isolated from both male and female beetles. Additional cultures of this organism were grown in 10 ml of the same medium, shaken for 24 h, and 0.1 ml α–pinene, purified by preparative gas chromatography, added for a further 24 h. Ether extracts of the cultures, and of

appropriate controls, were prepared and an aliquot of each extract analysed by gas chromatography on 10% EGS (140 °C) Peaks corresponding to both *cis-* and *trans*-verbenol were found in the culture extracts while none was detectable, even at high sensitivity, in the controls

The verbenols were purified from the remaining culture extracts by the consecutive separation, collection, and rechromatography of the appropriate peaks on four different stationary phases These were, in order of use, 10% Apiezon L (140 °C), 10% SP-1000 (140 °C), 10% EGS (140 °C), and 3% OV-225 (100 °C) Mass spectra of the purified substances eluting from the OV-225 column, at the same retention time as *cis-* and *trans*-verbenol, were recorded and the congruence of these spectra with those of standard spectra, also purified by gas chromatography, confirmed that both verbenol isomers had been synthesised from α-pinene by *B cereus* The yields of *cis-* and *trans*-verbenol were approximately 0 1% and 1% respectively of the added α-pinene Another major product of this transformation has been tentatively identified as myrtenol

α-Pinene   *trans*-Verbenol   *cis*-Verbenol

In spite of the numerous studies on the aggregation pheromones of *Ips*, the site of their synthesis has not been clearly defined Hughes[10] has argued that detection of the verbenols and other oxidation products in the haemolymph of the bark beetles, *D ponderosae* and *D valens*, after exposure to α- or β-pinene, established that their production occurs outside the alimentary canal It is assumed that these oxidation products are secreted into the hindgut and concentrated there by the reabsorption of water In contrast to this hypothesis, we consider that exposure of an individual beetle to the vapour of a particular monoterpene will saturate both the haemolymph and the gut contents with the monoterpene The oxidation of α- or β-pinene by microorganisms within the gut would then account for the greatly increased amounts of their oxidation products in this region and the detectable amounts in the haemolymph could occur either by diffusion out of the gut or by production of small amounts in the haemolymph, or by both processes

We have found that α-pinene, the most likely precursor of both the verbenols and myrtenol, is a major component of the monoterpenes present in the phloem of ponderosa pine Therefore, by either feeding or exposure, or both, this monoterpene would be present in the gut of male *I paraconfusus* during nuptial chamber excavation The occurrence of α-pinene throughout the gut of feeding *I calligraphus*[6] has been shown, and a number of *Dendroctonus* species produce increased amounts of the verbenols in their hindgut after exposure of individuals to α-pinene[8–10] These and other observations indicate that either ingestion of α-pinene, or intimate contact with α-pinene, or a combination of both of these conditions, is a prerequisite for the production of the verbenols by the various bark beetles It is obvious that under natural conditions of a beetle excavating a gallery both mechanisms would be operative *B cereus* present in the gut must come into contact with this monoterpene and presumably could bring about the oxidation of α-pinene to the verbenols Significantly, myrtenol is also known to be present in the gut of certain bark beetles after exposure to α-pinene[8,10]

A *Bacillus* sp capable of converting α-pinene to the verbenols has also been isolated from both males and females of *I grandicollis* and three species of *Dendroctonus* While our preliminary results do not prove conclusively that *B cereus* actually synthesises the verbenols from α-pinene in the hindgut, our data clearly indicate that this is a distinct possibility and substantiate the hypothesis that microorganisms may play a significant role in the synthesis of certain pheromones occurring

in the frass of these bark beetles The known differences in the quantitative production of the aggregation pheromones between males and females in these two genera remains enigmatic and is the subject of continuing investigations

Stability of feasible predator-prey systems

Roberts[1] added a new dimension to the stability analysis of model ecosystems—feasibility, the requirement that equilibrium densities of species be positive Previous work[2–4] studied the stability of randomly constructed interaction matrices, *S*, which represented ecological interactions in the neighbourhood of an assumed feasible equilibrium point

Investigating the normal sort of quasi-linear ecological model, from which both equilibrium densities and stability can be determined, Roberts concluded that "almost all feasible systems are stable when the number of interacting species increases without limit"[1] Since real ecosystems are, *ipso facto*, feasible, this implies large ecosystems are more stable than small ecosystems—the tropics are more stable than the arctics This is the first instance where it is claimed that mathematics has supported the conventional wisdom of the natural historians diversity begets stability Mathematical analysis, summarised by May[4], has controverted this, yielding a new conventional wisdom stability permits diversity Roberts used the model,

$$dN_i/dt = N_i(r_i - \Sigma_j a_{ij}N_j), \quad i=1 \text{ to } m, \qquad (1)$$

in which he assumed $r_i = 1$, $a_{ii} = -1$ and $a_{ij} = \pm z$ where $+$ and $-$ are equally likely I have investigated the feasibility and stability of this model as a function of the interaction strength, z, and the number of species, m (Table 1) I have done the same for a modified version of this model in which $r_i = \pm 1$ and $a_{ii} = \pm 1$ where $+$ and $-$ are equally likely, and where a_{ij} are as before (Table 2)

Table 1 Feasible cases in 500 randomly constructed instances of Roberts' model The stable cases are indicated in the parentheses

No of species (m)	Strength of interaction (z)					
	0 2	0 4	0 8	1 6	3 2	6 4
2	500 (500)	500 (500)	500 (500)	133(0)	129 (0)	125 (0)
3	500 (500)	395 (395)	411 (411)	95 (20)	86 (12)	101 (16)
4	500 (500)	305 (305)	260 (257)	51 (3)	35 (5)	21 (4)
5	480 (480)	193 (191)	136 (127)	24 (3)	28 (5)	19 (3)
6	446 (446)	116 (114)	77 (63)	8 (1)	9 (1)	12 (2)
7	389 (389)	58 (53)	34 (32)	3 (0)	3 (0)	3 (1)
8	328 (328)	31 (29)	17 (11)	1 (0)	4 (2)	2 (1)
9	262 (262)	11 (11)	4 (3)	0 (0)	4 (0)	1 (1)
10	228 (228)	7 (5)	2 (2)	0 (0)	1 (1)	1 (0)

For both models, feasibility decreases with increasing m Non-feasibility corresponds reasonably to the competitive exclusion of one or more species (It can mathematically, but unreasonably, correspond to ecosystems whose biomass grows exponentially without limit) Therefore, both models predict greater instability, in the sense of increased frequency of competitive exclusion, in randomly constructed systems with greater numbers of species This is certainly no support for the conventional wisdom of the natural historians

The two tables indicate, moreover, that the stable percentage of the feasible cases behaves differently for the two models, increasing with m in Roberts' model, decreasing with m in the second model This means, at least, that Roberts' conclusion is fragile—not robustly insensitive to his assumptions And it suggests that his results may be artefactual

This is certainly the case Because he assumed r_i to be positive for all values of i, each of his species is autotrophic, that is, each can grow in the absence of all other species Alternatively, the species are heterotrophs and their energy supplies are implicitly included Therefore there is neither predation nor resource competition in his model, but only interference and facilitation (each equally likely) between species on a trophic level Mutual interference is reasonable[6], but the other interactions between pairs are evolutionarily absurd Why should the members of one species facilitate the members of a species that are interfering against them? Furthermore, mutual facilitation does not commonly occur between species on the same trophic level (interspecific bird flocks may be a counter example) Odum[6] states, "mutualism is most likely to occur between organisms of widely different requirements"

The second model does permit multiple trophic levels and predator–prey interactions Even though it permits some[f] absurdities (1 eats 2, who eats 3, who eats 1), it is clearly a more reasonable model of ecological interactions than the model Roberts chose The conclusions from the second model are consistent with the mathematical analysis of diversity and stability summarised by May[4]

One apparent difference exists between the second model and May's work stability increases with z in the second model ($P < 0.01$), whereas it decreases with interaction strength in May's work The interaction matrix, a_{ij}, of the second model

Table 2 Feasible cases in 500 randomly constructed instances of the second model The stable cases are indicated in the parentheses

No of species (m)	Strength of interaction (z)						Average percentage stable
	0 2	0 4	0 8	1 6	3 2	6 4	
2	119 (22)	122 (29)	120 (28)	117 (39)	109 (39)	132 (43)	28 3 ± 3 0
3	67 (8)	57 (8)	49 (5)	62 (14)	69 (17)	61 (19)	19 1 ± 3 3
4	30 (3)	35 (0)	33 (3)	29 (7)	33 (7)	29 (4)	13 0 ± 3 6
5	17 (1)	20 (4)	17 (1)	15 (3)	22 (4)	10 (1)	13 0 ± 2 9
6	5 (0)	7 (1)	12 (0)	7 (0)	11 (0)	3 (0)	2 38 ± 2 3

Influence of menstrual cycle on volunteering behaviour

RANDOM population sampling is rarely achieved in human research Rosenthal and Rosnow[1] have concluded that human behavioural science is largely the science of punctual college sophomore volunteers Volunteers typically have more education, higher occupational status, earlier birth position, lower chronological age, higher need for approval and lower authoritarianism than nonvolunteers[2-9] We report evidence here to suggest that the volunteering behaviour of college women varies with the stage of their menstrual cycle This implies that many experiments which report perceptual, cognitive or physiological response differences between the sexes may be biassed in systematic fashion by sampling error

In the initial experiment, women from two sections of a University of San Francisco child psychology class completed, in class, a questionnaire consisting of eight items on attitudes towards family planning, alcohol and drug use on campus, and peer-group and parental relationships Each respondent's age, social security number, religion, average menstrual cycle length, use of oral contraceptives and date of onset of the most recent menses were also obtained Social security numbers were used for data tabulation and the respondents were assured that the information would be kept confidential and used only for scientific purposes Two days later a male social psychologist, not associated with the original questionnaire, was introduced to the class and briefly described a research project for which he needed volunteers For one section, the proposed project required that the volunteers work alone on a learning task For the other it required that they work as a group in a decision-making task Sign-up sheets were subsequently passed around the class As in many psychology classes, such requests for volunteers were a common occurrence

To establish whether the stage of the menstrual cycle was related to volunteering, the cycle of each woman not taking oral contraceptives was divided into five phases on the basis of the questionnaire data The midpoint of the 'ovulatory phase' was calculated from the reported average cycle length by subtracting 14 d The 2 d on each side of this midpoint

were included in this phase, making it 5 d long The 'menstrual phase' was calculated as 5 d extending from the onset of menstrual bleeding, the 'preovulatory phase' made up the days falling between the menstrual and ovulatory phases, whereas the 'postovulatory phase' made up the first half of the period extending from the end of the ovulatory phase to the beginning of the next presumed menses The second half of this period was termed the 'premenstrual phase'

Since the type of experiment did not affect the frequency of volunteering, the data for both lecture sections were combined and are presented in Table 1a Most of the volunteers were in the ovulatory phase, whereas most of the nonvolunteers were in the postovulatory, premenstrual and menstrual phases ($\chi^2 = 22\ 47$, d f $= 4$, $P < 0\ 001$)

To establish whether this phenomenon was dependent on the sex of the individual seeking volunteers, we repeated the experiment a year later in a different class section using a female social psychologist In this case, the questionnaire data were obtained on the same day as the request for volunteers Table 1b shows that the results were essentially the same as in the previous experiment ($\chi^2 = 25\ 31$, d f $= 4$, $P < 0\ 001$)

Direct evidence for this phenomenon is difficult to find in the literature, since few investigators report the testing order of volunteers within the menstrual cycle In a recent study of taste preferences, Wright and Crow[10] divided the menstrual cycle of their volunteer subjects into five equal phases It is interesting that the number of subjects tested in the five phases (sequentially from menses) was 9, 18, 24, 25 and 17, respectively ($\chi^2 = 8\ 88$, d f $= 4$, $0\ 05 < P < 0\ 10$) Many behavioural studies reporting sex differences have assumed a random distribution of volunteering during the menstrual cycle because no relevant data were collected, and even studies examining menstrual cycle phenomena directly have made such an assumption For example, the authors of one study[11] reporting changes in visual sensitivity during the menstrual cycle stated "Because they were initiated into the test program as they volunteered, session order for the females was independent of the phase of the menstrual cycle" Our results suggest that this assumption is questionable and that test order should be counterbalanced so that systematic order effects are not confounded with endocrine influences

Several explanations of our findings seem plausible Some women, at least in Western cultures, undergo cyclic changes in emotions during the menstrual cycle Premenstrual and menstrual increases in tension, irritability, depression, anxiety and fatigue have been reported, as have increases in elation and activity near the time of ovulation[12-14] Such psychological and physiological changes may influence directly the tendency of women to volunteer for research It is possible that tendencies to respond to convert or overt classroom teacher and/or peer-group pressure are related to changes in 'response criteria' noted in signal detection analyses of perceptual phenomena during the menstrual cycle[15]

Regardless of the specific causal factors involved, our results suggest that many experiments which use female volunteers test a disproportionate number whose hormonal status is skewed from that of the general population of females The degree of skewing would depend on factors such as the length of time between the act of volunteering and actual participation in the experiment If such participation has followed soon after the time of volunteering, much of the literature on human females may be representative of punctual college sophomore

Table 1 Number of volunteers and nonvolunteers in each of the five phases of the menstrual cycle

Phase	Menstrual	Preovulatory	Ovulatory	Postovulatory	Premenstrual
a Male experimenter					
Volunteers	0	7	14	5	3
Nonvolunteers	7	4	1	12	5
b Female experimenter					
Volunteers	3	2	7	1	0
Nonvolunteers	23	4	1	14	4

volunteers who are probably not menstruating and are of ovulatory status

Differential rates of cerebral maturation between sexes

TAYLOR and Ounsted[1,2] have proposed a model to account for the age of onset of developmental disorders and their relative incidence between the two sexes They propose that there is a period in the maturational continuum during which the child is particularly vulnerable to a particular disorder Males develop more slowly than females and they should therefore reach this "dangerous state" later, and take longer to pass through it It is therefore predicted for any developmental disorder, that males should show a later age of onset and a higher incidence than females[2], but that females are more likely to suffer seriously than males[1], (although this does not follow directly from the model) Evidence relevant to these predictions is reported here for congenital hydrocephalus

Medical records are available for 48 children who were referred to the Neurosurgical Unit at the Radcliffe Infirmary, Oxford, over the past 20 years, and who were diagnosed as suffering from congenital hydrocephalus In most cases there was no associated spina bifida cystica or other complex multiple congenital deformities For each patient, it was established whether surgical intervention had been necessary, or whether the hydrocephalus had arrested spontaneously (Table 1)

The series contained 33 males and 15 females This is equivalent to a sex ratio of 220 males for every 100 females, and differs significantly from equiprobability according to the binomial test ($z = 2$ 56, $P < 0$ 01, two-tailed test) The median age at which the boys were referred was 26 weeks, the median age at which the girls were referred was 7 weeks The Mann–Whitney U test demonstrated that the boys were significantly older when referred than the girls ($z = 1$ 69, $P < 0$ 05, one-tailed test)

In the case of 23 of the children (48%), the hydrocephalus

arrested spontaneously This compares closely with a figure o 46% reported by Laurence and Coates[3] from a much large series Considering boys and girls separately, it was found tha spontaneous arrest occurred in 17 (52%) of the boys, and in ((40%) of the girls Thus, the girls were more likely to require surgical intervention than the boys The difference is no statistically significant, however, according to a χ^2 tes which used the correction for continuity ($\chi^2 = 0$ 18, d f $= 1$ $P > 0$ 5) The median age at which a patient was referred if his hydrocephalus arrested spontaneously was 48 weeks, the median age at which he was referred if surgery was necessary was 17 weeks The difference between these two medians approaches statistical significance, according to a Mann–Whitney U test ($z = 1$ 82, $P < 0$ 1, two-tailed test) Both groups, however, showed the effect of sex on the age at which they were referred, described above

These results support the two principal hypotheses which can be derived from the model proposed by Taylor and Ounsted[2] Congenital hydrocephalus occurs in boys later and more often than it does in girls This constitutes further evidence for two generalisations in the epidemiology of disease females are susceptible earlier than males, yet males are more susceptible than females The model proposed by Taylor and Ounsted links these two generalisations by a single formal mechanism

If the necessity for surgical intervention can be taken as a sign of the severity of hydrocephalus, there is also some evidence for their assertion that diseases tend to occur more severely in females than in males This evidence is, however, not supported by statistics Nevertheless, the findings of this study suggest that research into developmental disorders may increase our understanding of the nature of sex differences and the processes of cerebral maturation

Nude mice with normal thymus

MICE homozygous for the mutation, nude (*nu*) have been reported to have no thymus[1], although they retain a pre-lymphoid thymic rudiment[2] Here, I report the occurrence of individuals that are by external signs (including hairlessness) a nude mutation but possess an apparently normal thymus

The outbred nude stock in this laboratory has been repeatedly reinforced with +/*nu* heterozygotes and some fertile *nu*/*nu* homozygotes (Laboratory Animals Centre, Carshalton) The ensuing appearance of 'nudes with thymus' suggested that this phenotype originated from Carshalton, but the alternative could not be excluded that either a new mutation or some infiltration of a hairless gene might have happened in this laboratory Similar findings were communicated to me by Dr D Wakelin of the Wellcome Laboratories for Experimental Parasitology at the University of Glasgow, who had obtained his breeding stock from me A Carshalton origin, however, seemed to be confirmed when in November, 1974, I obtained from there a large group of nude mice aged about 3 months Out of over 60 autopsied so far there was one with an apparently normal thymus and one with a minute 'thymus' These tissues are being examined

Table 1 Number of patients referred, by sex and age at referral

	Age (months)							
	0	1	2	3–5	6–8	9–11	12–23	24 and over
Males	1	5	3	7	5	3	5	4
Females	5	4	0	0	1	1	2	2

In an attempt to test the hypothesis that a crossing over
ight have occurred between the gene for athymia and a
parate, so far unsuspected, gene for hairlessness, 48 young
ere obtained from matings of animals supplied by Dr Wakelin
id known to have given previously at least one nude mouse
ith a thymus Although such phenotypes again occurred, not
single animal was found with a normal coat but no thymus
everal animals with unusually small thymuses were observed,
ut the significance of this is problematical

Work is continuing on the above and alternative hypotheses,
ich as selection of modifiers under systems of husbandry
here, in outbred stocks, nudes that happen to be fertile are
ivoured as breeders[3] The present interim report becomes
ecessary because of the hazard the occasional nude mouse
nth a normal thymus constitutes for the experimenter It is
ow advisable to ensure that all nude mice are tested for
thymia at autopsy

I thank Dr D Wakelin and Dr M Festing for help and
iscussion

Nonspecific and specific immuno-suppression in tumour-bearing mice by soluble immune complexes

SEVERAL reports have concerned themselves with specific
suppression (blocking) of tumour-immune responses by serum
factors from tumour-bearing animals[1-3], and nonspecific
depression of T lymphocyte responses in tumour-bearing
mice has also been described[4,5] Evidence exists that specific
blocking of lymphocyte-mediated immunity occurs by means of
either free antigen[6] or antigen–antibody complexes[7] It has
now been suggested that nonspecific suppression of lymphocyte
responses could also occur by means of immune complexes[8],
if one assumes that both T and B lymphocytes have F_c re-
ceptors for the antibody region of such complexes There
is a growing body of evidence for F_c receptors of T cells[9,10]
We have investigated the possibility that the nonspecific
depression of the T lymphocyte phytohaemagglutinin (PHA)
response seen in BALB/c mice carrying tumours, induced by
Moloney sarcoma virus (MSV) in the progressive phase of
growth[4], is caused by similar factors to those which cause
specific blocking in this system Our results suggest that while
tumour-specific blocking can be mediated by free antigen,
as well as antigen–antibody complexes, nonspecific blocking
of T-cell responses is mediated only by the latter

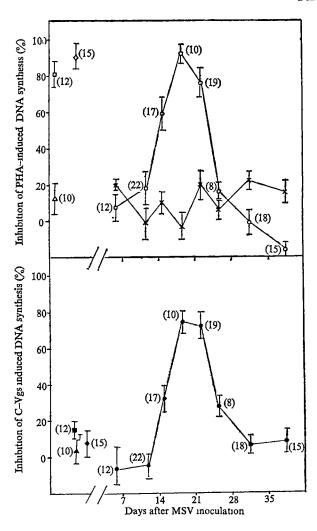
The technique for stimulation of DNA synthesis as an assay
for T lymphocytes responding to PHA or MSV tumour antigen
is reported elsewhere[4] A ^{51}Cr assay which measures specific
cytotoxic T lymphocytes was also used, the targets being
derived from MSV-infected mouse fibroblasts passaged once
through young BALB/c mice[11] All cultures were performed in
Dulbecco's modified Eagles MEM, supplemented with 10%
foetal calf serum (DF_{10}) Cells capable of nonspecific suppres-
sion of immune responses were obtained from spleen cells
from MSV progressor animals by velocity sedimentation[4]
Such cells represent that fraction of the total spleen population
which sediments with velocity 4 8–6 0 mm h^{-1} Mouse sera
were obtained by cardiac puncture, the serum being heat-
inactivated (56 °C for 30 min) and stored at −20 °C until use
Antigen–antibody complexes were eluted from the kidneys of
normal and MSV-infected mice by the method of Oldstone and


Fig. 1 Effect of tumour bearer and tumour regressor sera on
specific and nonspecific T-cell responses The assay used to test
for the suppression of the T lymphocyte response was to compare
the stimulation index

$$\frac{\text{c p m } ^3\text{H-thymidine incorporated in the presence of stimulus}}{\text{c p m } ^3\text{H-thymidine incorporated in the absence of stimulus}}$$

of 4×10^6 MSV regressor spleen cells (from mice given MSV 30 d
before) incubated in DF_{10} in the presence or absence of the
various sera For suppression of PHA responses (open symbols)
and LPS responses (crosses) the sera were used at a 1 10 final
concentration, for suppression of C-Vgs responses (closed
symbols) the sera were used at a 1 50 final concentration The
sera tested were ○, ●, ×, MSV inoculated animals, △, ▲,
normal mice, □, ■, polyoma tumour bearers, ◇, ◆, fibro-
sarcoma tumour bearers The number of mice used to provide
the pool of serum tested is shown in brackets beside the revelant
symbol All groups were set up in triplicate 95% confidence
limits are shown for each point The stimulation indices of the
MSV regressor cells used in the presence of DF_{10} alone were
PHA, 19±2 3, LPS, 23±4 1, C-Vgs, 6 2±1 2

Dixon[13] Rabbit anti-mouse immunoglobulin (anti-MIg)
columns were prepared as described previously[14] Absorption
of mouse sera on these columns (maximum capacity 2 mg
immunoglobulin) was performed at pH 7 0 in phosphate
buffered saline (PBS) Serum (0 5 ml) was washed on to the
column with 1 ml of PBS, the column left at room temperature
for 30 min, and the column was then washed with PBS until
the absorbance at 280 nm was less than 0 05 The absorbed
immunoglobulin was eluted at pH 2 6 with HCl glycine buffer.
The pH of the eluted immunoglobulin was adjusted to 7 0 with
phosphate buffer and both the unabsorbed effluent and the
eluted immunoglobulin were concentrated by vacuum dialysis
and dialysed against 200 volumes of PBS for 24 h

Figure 1 indicates the ability of serum taken from animals at
different times after MSV infection to inhibit the induction of
DNA synthesis by PHA, lipopolysaccharide (LPS), or MSV

Table 1 Effect of MSV sera or suppressor cells on response to PHA and C-Vgs

Velocity-sedimented suppressor cells added per culture	Final concentration of MSV serum present per culture	Stimulation index in response to	
		C-Vgs	PHA
None	None	5 5±1 1	24 ±3 6
2×10⁶		0 9±0 2	4 3±2 1
1×10⁶		1 1±0 3	6 2±2 1
0 2×10⁶		1 8±0 4	18 ±4 6
0 1×10⁶		3 2±0 5	19 ±3 7
	20%	0 8±0 3	2 6±1 3
	14%	0 9±0 2	6 3±2 1
	6%	1 2±0 2	10 5±3 2
	3%	2 9±0 5	18 ±4 1

2×10^6 spleen cells from MSV regressor animals (25 d after MSV inoculation) were cultured for 72 h in the presence of the stimulants shown (PHA, 1 μg ml⁻¹, C-Vgs, 5 μg ml⁻¹), with or without varying amounts of suppressor material All cultures were set up in triplicate The cultur were washed, pulsed for 12 h with 1 μCi of ³H-thymidine, and the TCA-precipitable material collected and counted in a liquid scintillatio counter The stimulation index was calculated as in the legend to Fig 1 95% confidence limits were calculated taking into account the variatio in both numerator and denominator

tumour-associated antigen (in this case a cell surface antigen with viral group specificity, C-Vgs) It is clear from these data that at around the time of tumour regression, serum factors appear which can block either of the T lymphocyte-mediated responses but not the B-cell response Moreover, the blockade of the C-Vgs response was mediated by lower concentrations of serum than were needed to cause nonspecific blocking The nonspecific blocking was seen with sera from other tumour-bearing mice (described elsewhere[15]), but the low concentration effect of serum on the C-Vgs induced enhanced DNA synthesis seems to be tumour specific[11] In our experiments normal mouse serum has never had a consistent suppressive effect on the splenic response to T or B cell mitogens (see Fig 1 and Table 2)

The correlation between the ability of sera taken from animals at different times after MSV infection to inhibit T lymphocyte responses in both a specific and a nonspecific manner agrees well with the simultaneous fall of each type of response in the spleen of MSV progressor animals[4] It is tempting to speculate that both the same serum factors and the same suppressor cell (already shown to be an immunoglobulin-bearing cell with sedimentation velocity 4 8–6 0 mm h⁻¹) cause these effects,

and that specific suppression is observed when the concentr. tion of suppressor is limiting Data to support this idea are show in Table 1 On dilution of sera or velocity-sedimented su pressor cells, the PHA response obtained from MSV regresso animals is restored before the C-Vgs response This is co sistent with the notion that the same cell type (or molecul produces each effect, the difference between seeing specific nonspecific inhibition being caused by the concentration cells (or molecules) needed to see each effect

In order to examine the possibility that immune comple cause both specific and nonspecific inhibition of T lymphocy function we have used an anti-MIg column in an attempt remove the blocking activity obtained from different source Three independent sources of blocking material have bee used (1) serum taken from mice 20 d after MSV inoculatio (Fig 1), (2) material eluted from the kidney basement mem brane of normal and the mice 20 d after MSV inoculation following a method previously described for obtaining immun complexes from such sources[13], (3) supernatants from 24 cultures of velocity-sedimented suppressor cells from MS' progressor animals, or their normal spleen cell equivalent Each supernatant was prepared from 1×10^8 cells, incubate

Table 2 Removal of blocking factors by an anti-immunoglobulin column

Source of blocking activity (concentration in PHA cultures, concentration with C-Vgs and in ⁵¹Cr assay)		Stimulation of DNA synthesis by		% Specific ⁵¹Cr release
		PHA	C-Vgs	
None		21 ±3 2	6 5±1 2	53±2 2
Normal serum (4mg ml⁻¹, 800 μg ml⁻¹)		22 ±2 6	6 7±1 1	52±1 9
20 d after MSV	Unfractionated (4 mg ml⁻¹, 800 μg ml⁻¹)	4 1±1 7	0 7±0 2	14±2 2
	Column effluent	16 ±2 7	2 8±0 3	40±1 7
	Column absorbed, acid-eluate	9 9±2 1	2 1±0 4	35±1 9
	Recombined fractions	6 8±2 4	1 3±0 4	15±1 5
Normal supernatant (400 μg ml⁻¹, 150 μg ml⁻¹)		22 ±1 7	6 7±1 3	52±2 1
Suppressor cell supernatant	Unfractionated (400 μg ml⁻¹, 150 μg ml⁻¹)	7 8±2 1	2 9±0 3	48±1 9
	Column effluent	19 ±2 6	5 8±0 5	50±2 2
	Column absorbed, acid-eluate	21 ±2 1	5 3±0 4	53±2 3
	Recombined fractions	17 ±3 2	6 2±0 3	51±1 9
Normal kidney extract (1 mg ml⁻¹, 300 μg ml⁻¹)		22 ±2 2	6 6±0 9	55±2 3
20 d after MSV	Unfractionated (1 mg ml⁻¹, 300 μg ml⁻¹)	5 1±1 6	1 3±0 2	17±1 9
	Column effluent	19 ±2 1	5 8±0 3	47±1 7
	Column absorbed, acid-eluate	18 ±3 1	6 4±0 9	51±2 0
	Recombined	8 2±3 3	3 1±0 3	28±2 2

Stimulation of DNA synthesis (using 4×10^6 regressor cells per culture) was as described in Table 1 and elsewhere[16] The final data are expresse as an arithmetic mean stimulation (compared with non-stimulated cells) with 95% confidence limits The ⁵¹Cr cytotoxic assay (final column) described in more detail elsewhere[11] Briefly, $7 5 \times 10^6$ regressor cells were incubated with 5×10^4 ⁵¹Cr lymphoma cells for 15 h at 37 °C, th final volume of the culture medium was 1 ml, and this medium also contained the blocking substances shown Percentage specific ⁵¹Cr releas was calculated as

$$\left(\frac{\text{c p m in supernatant with immune cells} - \text{spontaneous released c p m}}{\text{c p m in supernatant with detergent} - \text{spontaneous released c p m}}\right) \times 100$$

Normal cells routinely gave less than 0 5% specific release All cultures were set up in triplicate, the concentration of blocking factors in th tests used is shown in brackets thus (concentration with PHA as antigen, concentration with C-Vgs or lymphoma cells as antigen) Anti-MI column fractionated material was concentrated to the equivalent volume of the unfractionated materials

ı 5 ml serum-free Eagles' MEM with 5×10^{-3} M 2-mercapto-
thanol, and concentrated 30-fold by vacuum dialysis before
se

Each source of blocking material was tested with MSV
ıgressor cells in a DNA synthesis assay as in Table 1, and
ı a ^{51}Cr cytotoxicity test (with labelled MSV target cells)
'our fractions of each blocking material were analysed,
nabsorbed material, column effluent and acid-eluate, and the
ıtter two recombined at a 1 1 ratio The data for this experi-
ıent are shown in Table 2

Serum, kidney extract or cell culture supernatant derived
·om normal animals had no significant suppressive action
n the responses measured Whereas each of the unfractionated
locking materials derived from MSV-infected mice caused
oth anitgen-specific and nonspecific suppression of T-cell
ısponses, the effluent from an anti-MIg column (which we
resume contains free antigen) blocked only the antigen-
pecific responses (see effects of serum effluent on C-Vgs and
·HA induced DNA synthesis, and in the ^{51}Cr assay) The
olumn-absorbed, acid-eluted material, which could contain
xcess-free antibody and/or antigen-antibody complexes, again
·locked the antigen-specific responses, and often showed signi-
ıcant blocking of the nonspecific T cell response The best
uppression of the antigen-specific response, however, and often
he only suppression of the nonspecific response, was seen
·hen column-effluent and column-absorbed (acid-eluted)
naterial were recombined (giving antigen-antibody complexes,
ıerhaps in antigen excess) This is particularly well docu-
ıented for the MSV kidney extract, where only the recombined
naterial had any suppresive properties

We interpret these data as suggesting that optimum non-
pecific T cell blocking is mediated by antigen-antibody
omplexes, perhaps in antigen (column effluent) excess Antigen-
pecific T cell blockade is produced by lower concentrations
ıf such complexes, and, unlike nonspecific blocking, can also
ıe mediated by free antigen We feel that the failure to recover
ılocking activity from effluent, acid-eluate or recombined
naterial from the fractionated suppressor cell supernatant
·as a result of the low concentration of suppressor material
.pplied to the column in this case These findings do not
ıgree with an earlier report that in the MSV system in mice T
:ell cytotoxicity is not blockable by soluble tumour-associated
ıntigen (TAA) or progressor serum[3] The data do agree with the
eport that macrophage migration inhibition in this system,
ılso a T cell-mediated response[16], is inhibitable by progressor
era[17] A recent report indicates that T-cell-mediated cytotoxi-
:ıty in a rat Gross-virus induced lymphoma is also inhibitable
ıy soluble TAA or progressor sera[18]

It remains to be determined why T-cell cytotoxicity, which
s sensitive to lower concentrations of blocking factors in serum
ınd kidney extracts than the PHA response, is not blocked by
he suppressor cell fraction or culture supernatants which block
ıntigen-specific and PHA proliferative T-cell responses We are
nvestigating whether different TAA may be involved in T-cell
:ytotoxicity

Active suppressor mechanism maintaining tolerance to some self components

NORMAL mice have in their lymphoid tissues a fairly large
number of cells making antibody to antigens present within
isologous erythrocytes[1] These plaque-forming cells (PFC) are
readily seen on red blood cells (RBC) treated with bromelain,
or other proteolytic enzymes[1] DeHeer and Edgington[2] have
recently described similar PFC in NZB mice

Certain facts suggest that this constant level of PFC in
normal mice is maintained as a balance between two opposing
forces, continual antigenic stimulation by self antigens on
the one hand, and some suppressor mechanism on the other
Constant stimulation seems likely since the antigens form
part of normal mouse RBC and probably become exposed
as red cells degenerate CBA mice usually have 2,000–7,000
PFC on bromelain-treated RBC by 3 weeks of age, and main-
tain these plaques for many months at about this level, which
is some 20 times higher than the background to heterologous
RBC (ref 1) Germ-free mice have similar numbers of plaques[1]
Specific suppression as a force opposing further increases in
the numbers of these PFC is suggested by two observations
First, injecting bromelain-treated isologous RBC at a variety
of dosage and routes gives little or no increase in PFC on
similar target cells (ref 1 and A J C, unpublished) Secondly,
cells potentially able to make antibody or antibody-forming
progeny to the internal RBC antigens are probably numerous,
since mitogen (bacterial lipopolysaccharide from *Escherichia
coli*) induces enormous numbers of plaques (Fig 1)

A way of testing for suppressive effects was suggested by
the experiments of Baker and colleagues[3,4], who showed,
using antilymphocyte serum (ALS), that suppressor T cells

Fig 1 Effect of an intraperitoneal injection of 50 µg of lipo-
polysaccharide on numbers of plaques to bromelain-treated
isologous RBC in mouse spleen ●, Plaques on treated mouse
RBC using rabbit complement, O, PFC against normal sheep
RBC using guinea pig complement

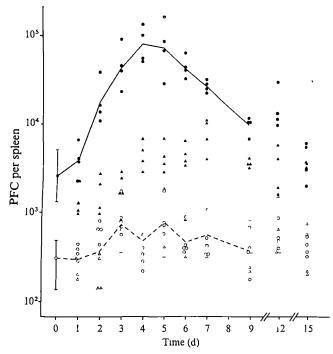
may diminish antibody responses to pneumococcal polysaccharide We made ALS by injecting rabbits intravenously with $2-10 \times 10^8$ mouse thymus cells on two to four occasions separated by intervals of 15–24 d Figure 2 shows that three injections of a total of 0 8 ml of this ALS increased the PFC numbers on bromelain-treated isologous RBC about 20-fold This is unlikely to have been a non-specific effect (that is, one caused by some general stimulation of immunocompetent cells), for several reasons The ALS had little or no effect on background plaques to sheep RBC (Fig 2), in sharp contrast to the stimulation of the anti-sheep response by mitogen (Fig 1) Normal rabbit serum had a much smaller stimulatory effect (Fig 2) In control experiments it was shown, first, that most of the activity of the ALS could be removed by absorbtion with mouse thymus cells, second, that the same pool of ALS decreased a response to injected sheep RBC about tenfold, and, third, by analogy with Baker's experiments[4], that the PFC number in nude mice was not increased by ALS injection, whereas that of their normal littermates was increased severalfold


Fig. 2 CBA mice were injected with 0 2 ml ALS intraperitoneally and 0 2 ml subcutaneously on day 0 On days 2 and 4, they received 0 1 ml in each site Control animals received serum from a normal rabbit ●, ALS injected, PFC assayed on bromelain-treated mouse RBC ○, ALS injected, PFC on sheep RBC ▲, Normal rabbit serum injected, assayed on bromelain-treated mouse RBC △, Normal rabbit serum injected, PFC on sheep RBC The day 0 points show geometric means and range of values in 12 uninjected mice tested on three different days

The simplest explanation for these results is that ALS promotes the autoantibody response by removing suppressor cells The suppressors may be T cells, although the evidence is not conclusive This example of suppressor tolerance to a group of self antigens in normal mice has obvious similarities to the active suppression, in young NZB mice, of responses to their own red cells[5,6]

It is important to determine the scope of this kind of mechanism by investigating a number of different model systems, since if tolerance to many self components, as well as to many foreign antigens[7], is maintained by active suppression of potentially reactive cells, a completely new view of the workings of the immune system would emerge In extreme form, this may be stated as follows All antigen-reactive cells bind some self components to varying extents, and all are subject

to some degree of continuous suppression (this is not to dei that deletion of some clones may occur if they are faced wii overwhelming amounts of a soluble self antigen which the bind avidly) The success of a foreign antigen in provoking specific immune response depends on its ability to distui this balanced state, with antigens close to self being most liab to suppression, and therefore least immunogenic During ar immune response, cells making entirely new antibody spec ficities are rapidly generated[8,9], and these new variants ai also liable to suppression, so that only those which mo successfully avoid the suppression mechanism are seen Coi stant stimulation with a foreign antigen leads to its beir treated like self[10] more, and perhaps new kinds of, suppresso cells develop, and a state of greatly reduced responsiveness t that antigen eventually supervenes

I thank Linda Pilarski and Peter Bretscher for discussion and Sue Fordham and Mary Johns for technical assistance

Separation of cells involved in phytohaemagglutinin-induced mitogenesis and cytotoxicity

LYMPHOCYTE mitogens such as phytohaemagglutinin (PHA) ma; induce lymphocytes to mitogenesis (DNA synthesis) an cytotoxicity (lysis of target cells) Although there is evidenc that these two responses are independent of each other i remains to be determined whether different lymphocyte sub populations are involved[1,2] It has been claimed that PHA is a selective T-cell mitogen but some recent work argues agains such precise specificity[3] There is also evidence suggesting that PHA may induce T cells to become cytotoxic but, since non-T cells may be cytotoxic under some conditions, the situation remains to be clarified[1,2,4–8]

In the course of investigation of the lymphocyte function o patients with immunological deficiencies, we have been im pressed by the frequent absence of PHA-induced mitogenesi; when PHA-induced cytotoxicity seems to be normal The reverse situation also occurs These observations suggested tha different lymphocyte subpopulations might be involved ir mitogenesis and cytotoxicity We report here evidence which shows that the cells involved may be separated by rosette sedimentation

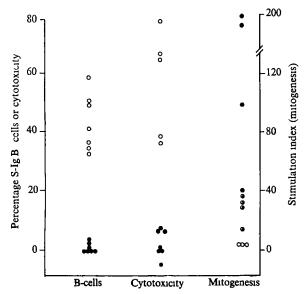
Between 50 and 100 ml of heparinised blood were collected from seven normal subjects and centrifuged on Isopaque–Ficol gradients[9] with a yield of 100–200 mononuclear cells per individual Polymorph contamination was less than 5% whereas the percentage of monocytes was variable The separated mononuclear cells were then incubated with sheep red blood cells (SRBC) so as to allow the formation on non-immune T-cell E rosettes[10] The mononuclear–SRBC mixture was then layered on to Isopaque–Ficol and centrifuged as for the initial separation The cells collected from the interface were found to contain less than 5% E rosetting cells and from 34–61% B cells as indicated by the presence of readily demon-


Fig. 1 The effect of rosette sedimentation on PHA-induced cytotoxicity, PHA-induced mitogenesis and B cells ○, Cells from the interface, ●, cells from the pellet, ◑, mononuclear cells before rosette sedimentation Stimulation index refers to counts after PHA stimulation divided by the resting level

trable surface immunoglobulin (S-Ig)[10] In contrast less than % and generally less than 1% of lymphocytes in the pellet were B cells with S-Ig Thus the interface population consisted f B cells with some "null" lymphocytes (non-E-rosetting, non--Ig) and some monocytes but very few E-rosetting T cells whereas the pellet population consisted of essentially pure T ells

These two populations were then compared in terms of PHA-induced mitogenesis and cytotoxicity The former was estimated by measuring the tritiated thymidine uptake after incubating 0^6 lymphocytes with 5 μl PHA-P (Difco) for 3 d Cytotoxicity was determined by counting ^{51}Cr release from 10^5 labelled chicken red blood cells after 18 h incubation with $2 5 \times 10^6$ lymphocytes and 10 μl of PHA[11] Contaminating SRBC were emoved from the pellet by lysis with 0 83% NH₄Cl–Tris-HCl pH 7 65) although in some experiments equivalent numbers of SRBC were added to the interface population

Results are summarised in Fig 1 There was a gross reduction in the PHA-induced cytotoxicity of the pellet population in relation to the interface population The reverse situation was seen with respect to mitogenesis induced by PHA The pellet population showed high stimulation indices relative to either the interface or the starting mononuclear population before rosette sedimentation

These data show that different subpopulations are involved in the mitogenic and cytotoxic responses to PHA It could be argued that the mitogenic response involves only E-rosetting T cells, but in other experiments we have found that there can be some stimulation of the interface populations and interpretation may be complicated by the fact that resting DNA synthesis is higher in the interface than the pellet population[12] For these reasons we cannot conclude that PHA mitogenesis is an absolutely specific T-cell marker but it would seem to be far more so than some others have suggested[3] E-rosetting T cells seem to contribute very little, if at all to PHA-induced cytotoxicity Whether B cells, non-E rosetting T cells, "null" lymphocytes or even monocytes are responsible for the cytotoxicity seen after incubation with PHA cannot be determined from the present study But we believe that our data clearly indicate that PHA-induced mitogenesis and cytotoxicity should be considered as representing different functions and populations when assessing patients with immunodeficiency states

Arthritis and Rheumatism Foundation, Muscular Dystrophy Associations of America and the Australian Kidney Foundation *Note added in proof* Work in progress (P J Z , G Grimsley and R L D , unpublished) suggests a major role for monocytes in PHA-induced cytotoxicity against RBC

Sertoli cell secretory function after hypophysectomy

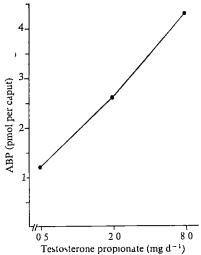
Testicular androgen is the principal stimulus for spermatogenesis[1] Androgens alone are capable of maintaining spermatogenesis in hypophysectomised rats when treatment is begun immediately following hypophysectomy[2] Following posthypophysectomy regression of the seminiferous epithelium, however, neither luteinising hormone (LH) nor androgen given alone is capable of initiating spermatogenesis when the same dose and time schedule is used for the treatment Follicle stimulating hormone (FSH) has to be given together with LH or androgen to effectively restore spermatogenic activity[1] This difference between main-


Fig 1 Maintenance of ABP production by testosterone propionate (TP) in hypophysectomised rats Male Sprague–Dawley rats in groups of four were hypophysectomised at 28 d of age and treated with various doses of testosterone propionate 0 5–8 mg d⁻¹ in sesame oil for 9 d, starting immediately after hypophysectomy The animals were then killed on day 10, testis and capita epididymides weighed and homogenised in four volumes of buffer (50 mM Tris-HCl, pH 7 4, containing 1 mM EDTA) and centrifuged at 105 000*g* for 1 h The supernatants were diluted with equal volumes of the same buffer containing 20% glycerol and 60 nM ³H-DHT Concentrations of ABP was then examined by steady state polyacrylamide gel electrophoresis (SS–PAGE) as previously described[11]

tenance (treatment started immediately after hypophysectomy) and initiation (treatment started after regression of the germinal epithelium) of spermatogenesis, has been known for more than 30 yr (ref 3), but no data have been provided which could explain this phenomenon

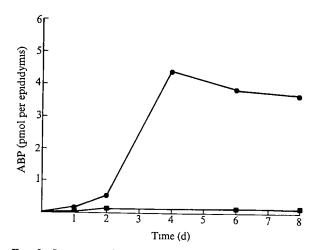
We have shown that one action of FSH in the seminiferous tubules is to induce the production of a specific androgen binding protein (ABP) by the Sertoli cells[4,5] This protein is secreted through the rete testis fluid and concentrated in the caput epididymis[6] We believe that the effect of FSH, mediated through ABP, is to amplify the testosterone stimulus to androgen-sensitive cells of the germinal epithelium Since ABP is produced in the Sertoli cell[7-9], we have suggested that this component can be used as a specific marker of Sertoli cell secretory function[10] We report here that androgen alone is capable of maintaining Sertoli cell secretory function in immature hypophysecto-


Fig. 2 Initiation of ABP production by FSH but not by testosterone propionate in hypophysectomised rats Rats (groups of four) were hypophysectomised at 28 d of age, and their testes allowed to regress for 10 d before testosterone propionate treatment Since 0 5 mg testosterone propionate daily was sufficient to maintain ABP in the capita epididymides for 10 d after hypophysectomy, animals were now treated with ten times this dose (■, 5 mg testosterone propionate daily) from 1–8 d starting at day 11 after hypophysectomy ABP was measured in capita epididymides using SS–PAGE as above Other groups of animals, hypophysectomised simultaneously, were injected with FSH alone (●, 250 μg NIH–FSH–S₁₀ per day) FSH was dissolved in saline containing 0 1% bovine serum albumin and 0 25 ml was injected subcutaneously twice daily (125 μg dose) TP was dissolved in sesame oil and 0 1 ml was injected intramuscularly once daily

mised rats, but is not able to restore the secretory activity of the Sertoli cell after posthypophysectomy regression

Figure 1 shows that androgen alone given to hypophysectomised animals is capable of maintaining Sertoli cell secretory function as measured by ABP levels in capita epididymides Increasing doses of testosterone propionate gave a dose-dependent increase in the amount of ABP per caput (Fig 1) as well as in testis weight (not shown) In the control animals (injected with oil only) no detectable ABP was present in the capita epididymides Figure 2 shows that androgen alone is not capable of stimulating ABP production by the Sertoli cell within 8 d of treatment Treatment with FSH, however, causes a rapid increase in ABP levels in the capita epididymides

We conclude, therefore, that the Sertoli cell is responsive to androgens as well as to FSH (refs 4–6 and 12–14) Following regression of the cells for 10 d without hormone stimulation (hypophysectomy), however, FSH is required for full restoration of the secretory capacity These studies also demonstrate the usefulness of ABP as a specific parameter of Sertoli cell secretory function

Occurrence of synapses in peripheral sensory nerves of arachnids

RECEPTOR cells of arthropods are presumed to send their axons directly into the central nervous system[1,2] Second order fibres supposedly do not occur in the periphery, an thus the first synaptic connections ought to lie within the ganglionic neuropiles We report, however, that synapse do occur regularly in peripheral sensory nerves of at leas two arachnid orders, whip spiders (Amblypygi) and harvest men (Opiliones)

The first legs of whip spiders are modified appendage which are extremely long (20–25 cm) and slender (0 2 mn diameter) The tarsi are subdivided into about 100 segment and bear thousands of multi-innervated hair sensilla[3] A there are no muscles within the tarsus, the two tarsal nerve consist of afferent fibres only (with the possible exceptio of some efferent fibres supplying epidermal glands)

Tarsi of the first legs of *Admetus pumilio* (Amblypygi were prepared for electron microscopy and transverse sec tions at various segments (2, 4, 6, 8, 10, 13, 15, 17 and 60 were examined Synapses were observed in most cros sections of the two tarsal nerves and occurred only on on or a few postsynaptic fibres (Fig 1a), which are alway located at the periphery of the nerve Thus, the synapse are restricted to a very small area, while the surrounding thousands of axons comprising the leg nerve do not exhibi any junctional specialisation

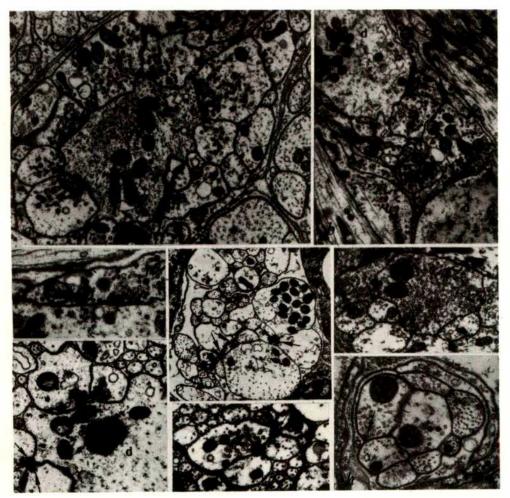
The postsynaptic fibre is relatively large Short latera extensions and the presence of ribosomes and many mito chondria suggest a branching dendrite The presynapti elements may form rather conventional synapses (Fig 1a or 'dyad' synapses[4-9] (Fig 1d) In the former case, there 1


Fig. 1 *a–e*, *Admetus pumilio* (tarsus of leg 1). *a*, Part of a cross section from a tarsal nerve showing one relatively large dendrite (d), contacted by about ten presynaptic endings (×15,400). *b*, Para-sagittal section corresponding to Fig. 1*a*. The synapses are not evenly distributed along the long axis of the dendrite (d) but form clusters at regular intervals. Most synapses (arrows) contain round synaptic vesicles and presynaptic dense projections. Some terminals exhibit flattened synaptic vesicles (asterisk) (×10,500). *c*, Detail of a longitudinally sectioned terminal. The contact zone is delineated by a widened synaptic cleft. Several dense projections, a cluster of synaptic vesicles and few dense-core vesicles (arrow head) are typical for the presynaptic side. The postsynaptic side shows very little, if any, membrane thickening (compare with *a*) (×18,350). *d*, Part of a cross section of a tarsal nerve. Two presynaptic fibres form dyad synapses with a large dendrite (d). Another dyad synapse is indicated by arrows (×22,800). *e*, A bundle of intra-epidermal nerve fibres in cross section. Short extensions of two large fibres receive dyad synapses (arrows) (×9,800). *f–g*, *Phalangium opilio* (tarsus of leg 2). *f*, Cross section of a tarsal nerve showing typical dyad synapses. The small fibre on the right (long arrow) forms perhaps a reciprocal synapse with the large fibre (short arrow) (×28,000). *g*, Intra-epidermal nerve fibre, densely filled with synaptic vesicles, makes dyad synapses (arrows) with several adjacent fibres (×15,700). *h*, *Araneus diadematus* (tarsus of leg 1). Eight intra-epidermal nerve fibres in cross section. One fibre (arrow) exhibits synaptic vesicles and a dense plaque opposite the angle between the adjacent nerve fibre and a glial cell (g) (×17,500).

high concentration of synaptic vesicles and a distinct synaptic cleft, yet little membrane thickening. The presynaptic side often has dense projections (Fig. 1*c*) but the postsynaptic side is only slightly thickened, if at all. The dyad synapse always involves three nerve fibres, usually two presynaptic axons and one postsynaptic dendrite. Both axon terminals have an electron-dense plaque on the cytoplasmic side of the membrane surrounded by a small cluster of synaptic vesicles. The typical arrangement of dyad synapses is shown in Fig. 1*d*.

Longitudinal sections show that the synapses do not cover the entire dendritic surface, but form clusters (Fig. 1*b*) at intervals of 6–8 μm. *En passant* synapses are commonly seen, which means that one presynaptic fibre often makes several synaptic contacts. Additional small synapses may be found in close proximity to the relatively large dendrites. From serial sections it seems that these contact dendritic extensions of the large fibre.

Synapses were also observed outside the tarsal nerves, within intra-epidermal fibre bundles (Fig. 1*e*). These also form either conventional or dyad synapses. In the latter case, several presynaptic fibres converge on a larger postsynaptic fibre.

The legs of harvest-men are especially long, and an investigation of the tarsal leg nerves in *Phalangium opilio* also revealed synapses, mostly of the dyad type (Fig. 1*f*) and seemingly not restricted to large postsynaptic fibres. One presynaptic axon often forms a dyad with two small postsynaptic fibres. This then represents a divergent synapse rather than the convergent type found in the whip spider. Definite synaptic contacts were also seen in intra-epidermal nerve fibre bundles (Fig. 1*g*).

A brief survey of the tarsus in a web spider (*Araneus diadematus*, Araneae) revealed synapses in the leg nerves as well as within intra-epidermal fibre bundles (Fig. 1*h*). These are, however, much less conspicuous and seemingly rarer than in the whip spider or harvest-man. Contacts similar to those shown in Fig. 1*h* have been reported in insect gustatory organs[10], and have been interpreted as efferent and assigned a 'neurosecretomotor' function. This is also a possible explanation for the intra-epidermal synapses found in arachnids, but it could hardly be applied to the synapses within the leg nerves, because there are no effector organs except for some gland cells.

How can the presence of numerous, often considerably localised, synapses in sensory nerves of arachnid legs be

interpreted? At present, the origins of pre- and postsynaptic elements cannot be clearly determined and no definite answer can be provided. It seems likely, however, that the large dendrites belong to interneurones which receive the input of many primary receptors. At least in the case of the whip spider, the system could be comparable with the giant fibre system found in many invertebrates[11-15]— except, of course, that the giant fibres lie within the central nervous system. In the whip spider the large fibres which receive synapses attain a diameter of 10 μm (proximal tarsal level), whereas the majority of sensory axons measure 0.2 μm or less. The large fibre diameter could provide a greater conduction velocity for nerve impulses; this may be an important feature, if one considers that most receptors are more than 20 cm away from the central nervous system. An additional advantage would be a reduction in the high number (10^4–10^5) of primary receptor axons.

From the large number of synapses occurring in peripheral sensory nerves, it must be concluded that some integration is taking place at the periphery of the arachnid nervous system. This may set the arachnids aside from insects, in which the first site of sensory information processing is believed to lie within the central nervous system[2].

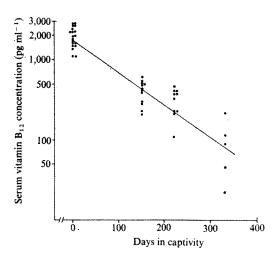
Neurological changes in fruit bats deficient in vitamin B$_{12}$

HAEMATOLOGICAL and neurological sequelae are the two major effects of vitamin B$_{12}$ deficiency in man. In the haemopoietic system, megaloblastic change leading to anaemia seems to be caused by deranged DNA synthesis[1]. The cause of central nervous system demyelination, however, is unknown and progress in this area has been hampered by the lack of a suitable experimental animal model. We report that Egyptian fruit bats (*Rousettus aegyptiacus*), made vitamin B$_{12}$ deficient in captivity, develop neurological changes similar to those observed in human subacute combined degeneration of the spinal cord.

Previous attempts to find a suitable animal model for vitamin B$_{12}$ deficiency have proved difficult for several reasons. Herbivores obtain vitamin B$_{12}$ either by coprophagy[2] or, in the case of ruminants, from resident microorganisms in their upper gastrointestinal tract[3]. Consequently, it has been necessary to impose a variety of artificial procedures, such as the use of synthetic diets[4], the prevention of coprophagy[5] and antibiotics to eliminate gastrointestinal flora[6], to produce vitamin B$_{12}$ deficiency in animals. Furthermore, animals made vitamin B$_{12}$ deficient by these procedures do not develop consistent haematological or neurological changes. The most convincing evidence of neurological change in vitamin B$_{12}$ deficient animals was reported in primates which developed


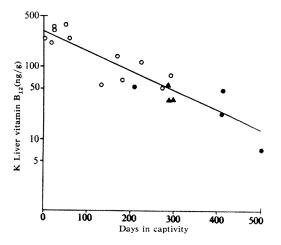


Fig. 1 Serum vitamin B$_{12}$ concentrations (log scale) at various times in 19 bats maintained on an all-fruit diet. The fall was exponential and highly significant after 330 d (t_{22} = 14.8, P < 0.001). The formula for the regression line was: $\log y = -0.0041 x + 3.245$ and the calculated turnover rate [$(\ln 2/t_{\frac{1}{2}}) \times 100$] was 0.93% d^{-1}.

'cage paralysis' on a vegetarian diet[7], but two recent studies failed to confirm these findings.

R. aegyptiacus (suborder Megachiroptera) is widely distribute in tropical and semitropical parts of the Old World. Th species has been successfully kept in European zoos since th last century[10], and its natural lifespan has been estimated be 15–20 yr[11]. We selected this species because its natural di consists entirely of fruit and flowers[10]. Also, because of the habit of foraging on fruit trees remote from the caves in whi they roost, faecal contamination of the diet is unlikely, ar furthermore, coprophagy has not been observed. Although is not known how these bats normally obtain their dieta supply of vitamin B$_{12}$, it is presumed that they may do so eith by inadvertent ingestion of fruit pests, or by drinking stagna water which may contain up to 1.0 ng vitamin B$_{12}$ ml^{-1} (ref. 12 We excluded these potential sources of the vitamin in captivi without otherwise altering the bat's natural diet.

Adult male bats captured in the North-eastern Transva were maintained on a pest-free all-fruit diet consisting washed and peeled bananas, papayas, pears and orang fed *ad libitum*. Bats were supplied with clean tap water dai and their cage floor was kept clean. Blood samples we

Fig. 2 Liver vitamin B$_{12}$ concentration (log scale) in 19 bats which were killed at various times while on an all-fruit diet. The fall was exponential and highly significant (t_{17} = 24.6, P < 0.001). The formula for the regression line was: $\log y = -0.0029 x + 3.061$ and the calculated turnover rate was 0.63% d^{-1}. Presence or absence of neurological changes shown by: ●, functional and structural abnormalities; ▲, functional, but no structural abnormality; ○, normal.

obtained by direct cardiac puncture for blood counts and measurement of the serum vitamin B_{12} concentration using a radioisotope dilution method[13]. Liver vitamin B_{12} concentration was measured by a modification of the serum method. Stained slides were prepared from rib bone marrow. Spinal cords were removed from freshly killed animals, sectioned and stained with haematoxylin and eosin, phosphotungstic acid haematoxylin, the Kluver–Barrera stain for myelin, Bielschowsky stain for axons and oil red O for lipids.

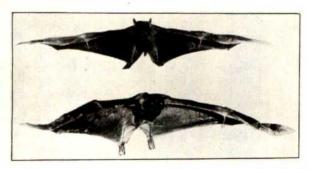
The serum vitamin B_{12} concentration (mean $\pm$ s.e.) in 19 bats fed this diet fell significantly from 1964.0 ± 121.01 pg ml^{-1} at the time of capture, to 98.6 ± 34.88 pg ml^{-1} in five surviving bats after 330 d (Fig. 1). The liver vitamin B_{12} concentration measured in bats killed at various times also fell significantly (Fig. 2). Over this period, there was no fall in the haemoglobin level, haematocrit or red cell count, nor any alteration in the calculated red cell indices. But the leukocyte count (mean $\pm$ s.e.) in 19 bats fell significantly from 19.5 ± 1.11 to 4.9 ± 0.38 thousand μl^{-1} in 12 surviving bats after 130 d ($t_{29} = 12.5$, $P < 0.001$). This fall reflected a decrease in both granulocytes and non-granulocytes, but no further significant change was observed beyond 130 d. Injection of 200 ng vitamin B_{12} per week in two bats resulted in a return of the leukocyte count to initial values. There was no increase in polymorphonuclear leukocyte lobe count, nor was there bone marrow evidence of megaloblastic change in either myeloid or erythroid precursors.


Fig. 3 Single representative frames of (*a*) normal and (*b*) deficient bats, taken during middle of downstroke. Three major functional alterations occur in the flight pattern: Gross irregularities of the surface of the dactylopatagium result in massive turbulence and partial stalling; the irregular surface of the tip negates the propulsive force normally arising from the downward twist of this region; slackening of the trailing edge (normally held taut between foot and fifth digit) increases drag.

After 200 d, as bats became progressively more vitamin B_{12} deficient (Fig. 2) seven of the ten surviving animals developed ataxia, manifested by difficulty in climbing. This seemed to result from a loss of reflex proprioceptive sensation in the lower extremities, as bats were unable to disengage their claws from the wire mesh during climbing.

Changes in the normal flying cycle were also noted, and were analysed by high speed cine and still photography. The most obvious abnormalities occurred during the downstroke, when the dactylopatagia were crumpled and irregular compared with the normally smooth, fully extended wing surface (Fig. 3). Full separation of the phalanges was lost, resulting in laxity of the individual membranes. At the beginning of the downstroke, when usually the phalanges are fully extended and radially deviated, those of the deficient bats trailed in the slipstream. The relatively coarser control of the shoulder, elbow and thumb was little affected but the weakened fifth digit led to slackness of the trailing edge of the plagiopatagium. The upstroke, being partly a passive phenomenon and requiring little precise aerodynamic control of the distal wing, was minimally affected.

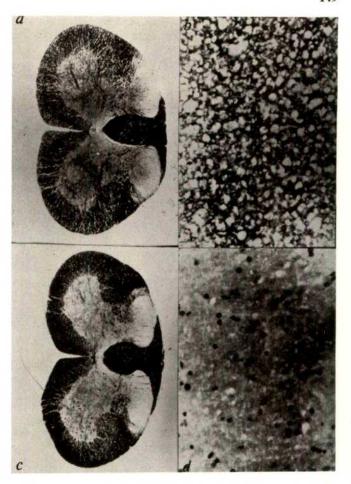
Histological sections of the spinal cords of bats killed after 200 d and stained for myelin, showed patchy spongiose change


Fig. 4 Histological sections of the spinal cord taken from the upper thoracic region of fruit bats. Sections stained with Kluver–Barrera stain for myelin. *a*, Low power view ($\times$ 14) of section from a vitamin B_{12} deficient bat (serum vitamin B_{12} concentration 108 pg ml^{-1}; liver vitamin B_{12} concentration 54 ng g^{-1}) obtained 210 d after receiving an all-fruit vitamin B_{12} deficient diet. The white matter shows patchy spongiose change affecting mainly the lateral and ventrolateral columns. *b*, High power view ($\times$ 259) of the white matter from the same section (deficient bat). *c*, Low power view ($\times$ 14) of section from a normal bat (serum vitamin B_{12} concentration 2,340 pg ml^{-1}; liver vitamin B_{12} concentration 320 ng g^{-1}). *d*, High power view ($\times$ 259) of the white matter from the same section (normal bat). The section from the normal bat does not show the patchy spongiose change seen in the spinal cord of the vitamin B_{12} depleted animal.

in the white matter of the lower cervical and upper thoracic region, mainly affecting the lateral and ventrolateral columns and suggestive of early demyelination (Fig. 4). The changes were observed in four out of five bats which had developed evidence of functional neurological impairment; their liver vitamin B_{12} concentrations are shown in Fig. 2. The lesions are similar to those lesions found in vitamin B_{12} deficient humans except that histological changes in man affect mainly the dorsal and lateral columns[14]. There was no evidence of reactive astrocytosis or gliosis, and the stain for axons showed no differences compared with normal cords. No lipid-containing phagocytes were observed on an oil red O stain. Bats given 200 ng cyanocobalamin per week by intramuscular injection did not develop any neurological changes, but cyanocobalamin supplements failed to reverse functional changes once they had appeared.

In summary, we have shown that the fruit bat can be rapidly depleted of vitamin B_{12} when kept on a diet similar to its natural one and that fruit bats may be used as an experimental model to study the neurological changes produced by vitamin B_{12} deficiency in the absence of anaemia. Further studies are in progress on the nature of these neurological changes.

Evidence for the B_{12}-dependent enzyme ethanolamine deaminase in *Salmonella*

THE enteric bacteria *Escherichia coli* and *Salmonella typhimurium*, like man, do not synthesise significant amounts of cobalamin (B_{12}) compounds and thus depend on exogenous vitamin B_{12} for their B_{12}-dependent enzymes[1]. In *E. coli* and *S. typhimurium* the only reported B_{12}-dependent enzyme catalyses the final step in methionine biosynthesis—the methylation of homocysteine to give methionine. These bacteria do not depend on exogenous B_{12} for growth, however, for they have an alternative B_{12}-independent homocysteine transmethylase (non-B_{12} enzyme) which can catalyse the same reaction. The non-B_{12} transmethylase is much less efficient than the corresponding B_{12}-dependent enzyme: in bacteria grown in the absence of vitamin B_{12}, the non-B_{12}-dependent enzyme comprises 3–5% of the total soluble protein[2]. If this enzyme is blocked by mutation, the mutant bacteria require either methionine itself or exogenous B_{12}, which allows them to utilise the B_{12}-dependent enzyme for methionine bio-synthesis[3]. We have sought other B_{12}-dependent enzymes in *S. typhimurium* and found evidence for an ethanolamine deaminase. We did not find other examples of parallel non-B_{12}-dependent and B_{12}-dependent enzymes in *S. typhimurium*. *E. coli* also seems to have an ethanolamine deaminase.

We first searched for B_{12}-dependent catabolic enzymes, since other bacteria use such enzymes in major catabolic pathways for arginine, lysine, ornithine, propanediol, glycerol, glutamate and nicotinate[4]. If *S. typhimurium* or *E. coli* have similar B_{12}-dependent catabolic pathways, they would have gone unnoticed in surveys of utilisable carbon and nitrogen sources performed in the absence of exogenous B_{12}. Petri dishes of carbon-deficient or nitrogen-deficient medium were seeded with about 2×10^8 cells of wild type *S. typhimurium* LT 2 and a few µg of each test compound was added to the surface of the plate and incubated at 37 °C (ref. 5). Each substance was tested in the presence or absence of vitamin B_{12} (cyanocobalamin, 0.4 µg ml^{-1}). Growth was observed daily for a week. Ethanolamine was found to serve as a source of nitrogen in the presence of vitamin B_{12}.

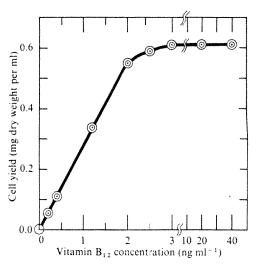
With B_{12}, ethanolamine supported as much growth as did ammonium. The final growth yields were the same, regardless of whether ethanolamine or NH_4Cl was used as the nitrogen source in a minimal medium containing vitamin B_{12}, glucose and


Fig. 1 Growth of *Salmonella* on ethanolamine and vitamin B_{12}. The growth medium was T2 salts mixture[8] supplemented with 0.5% glycerol, 7.4 mM ethanolamine hydrochloride, and the indicated quantities of vitamin B_{12}. Cultures were shaken for at 37 °C. After 34 h of incubation, cell yields were determined by measuring the 650 nm absorbance of cell suspensions.

salts. With ethanolamine, the doubling time was about 10 min, with NH_4Cl, about 50 min.

Vitamin B_{12} was essential for the utilisation of ethanolamine At low B_{12} concentrations, the growth of *S. typhimurium* wa proportional to the concentration of vitamin (Fig. 1). Colbaltou chloride did not satisfy the vitamin B_{12} requirement, indicatin that the synthesis of B_{12} compounds in *Salmonella* is not limite by the availability of cobalt.

Ethanolamine may also serve as a poor carbon source wit B_{12}. After 36 h of incubation on carbon-deficient solid medium there was slight growth around filter paper disks saturated wit a solution of ethanolamine.

Many members of the Enterobacteriaceae may be able t utilise ethanolamine as a nitrogen source in the presence o exogenous vitamin B_{12}. *E. coli* (K12) and *Enterobacter aerogene* (ATCC 1033) showed the same response as *S. typhimurium* t vitamin B_{12} and ethanolamine. Turner *et al.* have reported[6] tha *Erwinia* spp. utilise ethanolamine as a nitrogen source, but ther is no specific evidence for a B_{12}-dependent pathway.

We next used penicillin selection procedures to determin whether homocysteine transmethylase is the only system i which *S. typhimurium* has alternative B_{12}-dependent and non B_{12}-dependent enzymes. If other systems are catalysed b alternative B_{12}-dependent and non-B_{12}-dependent enzymes, i should be possible to inactivate the latter enzymes by mutation mutants lacking the non-B_{12}-dependent enzyme should requir exogenous B_{12} for the corresponding B_{12}-dependent enzyme Mutants were induced by saturating a fully grown culture o *S. typhimurium* LT 2 with diethylsulphate and incubating it fo 10 min. A sample (0.1 ml; 2×10^8 cells) of this culture was the transferred to 5 ml of nutrient broth and grown overnight. The 0.1-ml portions of the culture were collected on Millipore filter and subjected to selection[7]. After treatment with penicillin, th cells were filtered, washed and grown in a minimal glucos medium supplemented with vitamin B_{12}. Clones derived from these cultures were tested for their ability to grow on minima glucose medium with and without methionine or vitamin B_{12} supplements. All incubations were at 37 °C. From 217 survivor of the selection procedure, we obtained 89 B_{12}-requirin mutants, all of which grew in the presence of either vitamin B_{12} or methionine. They were presumably all *metE* mutants whic lack the non-B_{12} enzyme in the methionine pathway.

We then modified the penicillin selection procedure to exclud methionine mutants. Methionine (0.2 mM) was added to th penicillin solution. Any methionine auxotrophs would then b killed by the penicillin. Any B_{12}-requiring mutants which do no respond to methionine, would presumably have lost the non-B_1

)art of some metabolic system which normally has alternative B_{12}-dependent and non-B_{12}-dependent enzymes We obtained 10 mutants of this type, even after two sequential selection operations on four mutagen-treated cultures This technique should have yielded mutants occurring at frequencies as low as 10^{-8} per mutated cell

The failure to obtain mutants in the second series of penicillin selection experiments suggests that only the methionine biosynthetic system has alternative B_{12}-dependent and non-B_{12}-dependent enzymes Other explanations for our failure to isolate mutants could be (1) the penicillin selection procedure was not as efficient as expected, (2) the traces of B_{12} found in *S typhimurium* were sufficient for growth, thus preventing the isolation of B_{12} auxotrophs, or (3) the systems using alternative B_{12}-dependent and non-B_{12}-dependent enzymes are not needed for growth under laboratory conditions The first explanation is unlikely, however, since so many B_{12}-requiring methionine mutants were isolated in the first selection experiments The second explanation is unlikely unless the hypothetical B_{12} enzyme has a much higher affinity for B_{12} and is required in much smaller amounts than the methionine biosynthetic enzyme

Our nutrition experiments suggest that *S typhimurium* and *E coli* have a B_{12}-dependent ethanolamine deaminase (ethanolamine–ammonia–lyase, EC 4 1 3), analogous to the enzyme in clostridia[8] It seems pertinent that these organisms have two B_{12}-dependent metabolic pathways and yet they cannot synthesise significant amounts of the B_{12}-compounds Under the usual laboratory conditions, neither pathway is essential for growth methionine can be made by the B_{12}-independent pathway and ethanolamine is not usually needed as a nitrogen source Nevertheless, the fact that the bacteria have both pathways suggests that they are at times advantageous and that the bacteria often have exogenous supplies of B_{12} compounds This is not surprising, since faeces and sewage are rich sources of vitamin B_{12} and related compounds

Drugs blocking the muscle-damaging effects of 5-HT and noradrenaline in aorta-ligatured rats

USING an animal system proposed as a model for the hypothesis that Duchenne muscular dystrophy might be caused by an impaired blood supply within muscle[1-3], we have found that certain drugs prevent the muscle damage typical of this disease The model involves combining ligature of the aorta with a minimal dose of serotonin (5-hydroxytryptamine, 5-HT) or noradrenaline to produce myopathy of the lower extremities, which is evident in histochemical changes[3] and increased amounts of some muscle enzymes in the plasma[4]

Imipramine (IP), phenoxybenzamine (PBZ) or chlorproma-

zine (CP), dissolved in normal saline, were injected intraperitoneally into 793 male Osborne–Mendel rats (150–175 g) which had been double-ligatured below the renal arteries[3,4] Beginning on the fifth day after ligature, the animals were pretreated with daily injections of one drug for 3 d On the eighth day after ligature, 8 h after the last injection, half the animals were given a dose of 5-HT (10 mg kg^{-1}) and half were given noradrenaline (3 25 mg kg^{-1}) Twelve hours after the 5-HT or 5 h after the noradrenaline they were bled terminally into preheparinised syringes by cardiac puncture under light pentobarbital anaesthesia The blood was cooled and cold-centrifuged at 17,750g for 2 min, and the plasma was pipetted off for enzyme analysis

For glutamic-oxaloacetic transaminase (GOT) we used the Reitman–Frankel method (U ml^{-1}), for lactic dehydrogenase (LDH), the Babson–Phillips method (IU), for creatine phosphokinase (CPK), the Rosalki method (μU ml^{-1}), and for alkaline phosphatase, the Babson–Phillips method (U ml^{-1})[4] The drugs were given to groups of animals in scaled doses IP (297 animals) 1 25, 2 5, 5, 10, 20 mg kg^{-1}, CP (301 animals) 2 5, 5, 10 mg kg^{-1}, PBZ (195 animals) 2 5, 5, 10, 20 mg kg^{-1}

Immediately after ligature the first four plasma enzymes increased prominently but all returned to normal by the fifth day[4] (40 animals) 5-HT or noradrenaline in the doses used, when not preceded by ligature of the aorta, caused no significant increase in enzyme activity[4] Peak increases occurred in ligatured animals 12 h after 5-HT (ref 4) and 5 h after noradrenaline (determined in this study using 52 animals analysed 1, 2, 3, 4, 5, 8, 12 and 16 h after injection) In neither the test-control group nor any of the ligatured animals given IP, PBZ or CP before 5-HT or noradrenaline was there a significant increase in alkaline phosphatase, suggesting that liver damage was not the cause of plasma GOT, GPT, CPK and LDH increases For the purpose of this study we therefore term them muscle enzymes Injections of ligatured animals for 3 d with the largest doses of IP, PBZ or CP alone did not alter plasma enzyme values Animals receiving IP and PBZ (housed 3–5 per 27×44 cm plastic box) were not noticeably more active or less active than controls, but those given CP were slightly sluggish

The increase in all four plasma muscle enzymes provoked by a single dose of 5-HT was prevented, in a consistent relation to dose, by prior IP, PBZ or CP (Figs 1–3), the most complete effect was with IP (10 and 20 mg kg^{-1}), subsequent doses of 5-HT having almost no effect on enzyme activity (Fig 1) The increase in muscle enzymes was prevented in a similar manner when PBZ and CP were given before noradrenaline (Figs 2 and 3) IP before noradrenaline, however, had two opposite effects, depending on the dose small doses (1 25 and 2 5 mg kg^{-1}) significantly prevented the induced increase of all the enzymes, while the largest dose (20 mg kg^{-1}) markedly enhanced the increase of CPK and LDH (and had no net effect on GOT and GPT) Thus, the largest dose of IP had opposite effects on the presumably indirect muscle-damaging actions of 5-HT and noradrenaline (Fig 1)

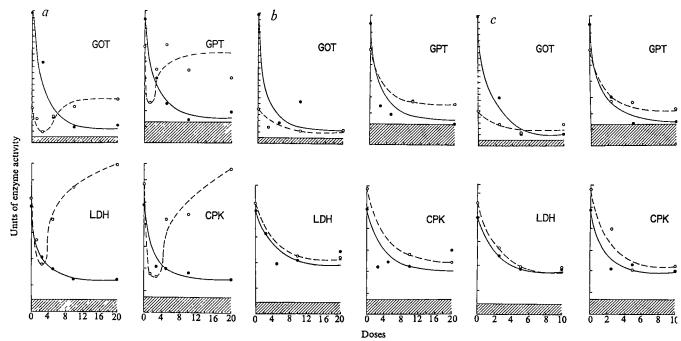
The muscle damage caused by low doses of 5-HT or noradrenaline given to aorta-ligatured rats is probably the result of ischaemia[1 3] The protective effect of pretreatment observed with PZB or CP before noradrenaline or 5-HT may be related to the known ability of both to block the action of α-adrenergic agents as well as responses to 5-HT[5-7] The enhancing effect of high doses of IP on muscle damage induced by noradrenaline may be related to the known ability of IP to reduce uptake of noradrenaline into nerve terminals[5,8] Since IP also reduces such uptake of 5-HT[9,10], the reason for its action in blocking the 5-HT effect in our animals at all doses and the noradrenaline effect in low doses must be explained otherwise, perhaps related to the following IP often causes orthostatic hypotension and it can antagonise or reverse the local vasoconstrictor action of noradrenaline[6], presumably by α blocking (although desmethyl-IP can block release of noradrenaline from nerve endings[5]), and it can block the spasmogenic effects of 5-HT on the smooth muscle of isolated guinea pig ileum[6] It is possible that, at certain IP doses, analogous mechanisms predominate in the


Fig. 1 Mean values (40–75 animals for each point) of plasma enzyme levels of GOT, GPT, LDH and CPK in aorta-ligatured rats given a single dose of 5-HT (●) or noradrenaline (○), pretreated by *a*, imipramine, *b*, phenoxybenzamine, or *c*, chlorpromazine Doses of pretreatment drugs on abscissa are given in mg kg^{-1} Divisions on the ordinate are GOT 100, GPT 20, LDH 100 and CPK 100 U of enzyme Zero point on the abscissa indicates enzyme level in control animals ligatured and given 5-HT or noradrenaline but no pretreatment drug, cross-hatched region indicates maximal upper range (on ordinate) of enzyme level in normal ligature-only rats, which is the same as in normal rats

smooth muscle of the abnormal (underperfused) intramuscular arterial vessels of our model

We conclude that this is a useful animal test system for evaluating interaction of drugs which affect muscle, presumably by acting on the intramuscular arterial system If the muscle-damaging mechanism in our model is, in principle, analogous to that in Duchenne muscular dystrophy, these experiments profile screening data of possible clinical relevance Because local metabolic factors are thought to be producing maximal vascular deconstriction in ischaemic regions of normal muscle[7], blockers of amine-induced vasoconstriction in normal persons may only be able to open collateral feeding vessels In Duchenne dystrophy muscle, however, we propose that there could be an inherited defect making small arterial vessels hyposensitive to deconstrictive local metabolic factors and/or overly sensitive to other constrictive ones such as vasoactive amines, defects for which amine-blockers might be at least partially corrective

The pertinence of our model, involving aorta ligature and vasoactive amine in low dosage, to Duchenne dystrophy has recently been questioned and an alternative one proposed— IP plus 5-HT at very high doses (10 times that used in our experiments) in non-ligatured rats[11] Pretreatment with IP had only a worsening effect (histologically) on muscle damage produced by the very high doses of 5-HT[11] Nevertheless, in Duchenne dystrophy patients we favour the mechanism/model of a small amount of vasoactive substance interacting with an underlying arterial vessel abnormality because they have no systemic evidence of large circulating amounts of vasoactive amine

Fluorescence techniques for following interactions of microtubule subunits and membranes

There is increasing evidence that several cell functions are controlled by the state of polymerisation of microtubules (MTs) and by the interaction of MTs with membranes For example, previous studies in our laboratory have shown that colchicine-sensitive structures, presumably MTs, determine the topographical organisation of cell membrane components[1-3] Conditions for the polymerisation of MTs *in vitro* have been described[4] The MT subunit has been identified by centrifugation studies as a 6S dimer of approximately 110,000 daltons[5] An additional 36S component is required for MT assembly[6] The established procedures used, however, to record MT polymerisation (light scattering and viscosity measurements supplemented by negative staining and electron microscopy) do not reveal details of the interactions between subunits undergoing polymerisation and cannot be applied in the presence of elements such as membranes that contribute separately to light scatter and viscosity

We report here a new method to monitor MT polymerisation and to investigate interactions between MTs and membranes Our approach involves long range resonance energy transfer between different fluorescent moieties separately conjugated to different MT subunits or to membranes The method permits study of weak or readily dissociable interactions between membranes and MTs or between subunits, which may not

survive techniques that physically separate or dilute the complexes

Resonance energy transfer occurs when a chromophore which is excited by the absorption of energy transmits the energy to another (acceptor) chromophore some distance away This transmission requires the overlap of the emission spectrum of the first (donor) chromophore with the absorption spectrum of the acceptor, but it does not involve the actual reabsorption of light by the acceptor It is therefore referred to as non–radiative or resonance energy transfer Resonance transfer requires that the distance between the chromophores be relatively close (not exceeding 100 Å) and in fact quantitative theory allows one to estimate the distance between chromophores from the extent of energy transfer[7–10]

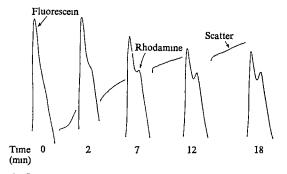
In our experiments fluorescein isothiocyanate (FITC) was used to label one population of MT subunits (protein dimers called tubulin and designated T) or membranes, and rhodamine isothiocyanate (RITC) was used to label a second population of tubulin These chromophores were chosen because they bind covalently and because the emission spectrum of fluorescein (donor) extensively overlaps the absorption spectrum of rhodamine (acceptor) In the non-polymerised state a mixture of fluorescein–labelled (F-T) and rhodamine-labelled (R-T) tubulins does not show resonance transfer With polymerisation (or aggregation) of MT-subunits, however, the chromophores are brought sufficiently close together so that energy transfer occurs The degree of transfer is thus dependent on the number of units polymerised Figure 1 shows a time course of the polymerisation of MTs followed by light scattering and resonance energy transfer The progressive increase in scatter was the same whether or not dye was conjugated with the tubulin, indicating that these low concentrations of bound chromophores do not interfere with MT assembly At the same time resonance transfer of energy from fluorescein to rhodamine was measured by exciting the sample at 480 nm, and recording the emission spectrum between 500 and 620 nm (to include


Fig 1 Time course of light scattering and fluorescence emission spectra during MT polymerisation Tubulin (T) was purified from rabbit brain by successive cycles of polymerisation and depolymerisation as described by Shalanski[11] Protein–dye conjugates were formed by incubation of purified protein (4 mg ml^{-1}) with fluorescein isothiocyanate (FITC) or rhodamine isothiocyanate (RITC) for 30 min at 4 °C Incubation was stopped by separating the conjugates from the free dye by column chromatography (Sephadex G–25) Dye to protein molar ratios (D/P) were determined by absorbance measurements using extinction coefficients of the bound dyes[12] and protein measurements by the method of Lowry[13] The absorbances of the mixtures followed spectroscopically did not exceed 0 20 absorbance units In this experiment incubations of 10 µg dye per mg protein and 5 µg mg^{-1} protein for RITC and FITC respectively gave approximate D/P values of 0 35 for R-T and 0 08 for F-T Tyndall scatter was measured at 650 nm using parallel polarised light, monitored at 90° to the incident beam (This assures a high signal to noise ratio) Viscosity changes (not shown) agreed closely with the time course of scatter measurements At intervals the latter were interrupted and emission spectra obtained by exciting the sample at 480 nm and scanning from 500 to 650 nm Corrected spectra were obtained using a Perkin–Elmer MPF4 fluorometer At zero time a single peak representing only fluorescein emission was obtained A rhodamine emission peak developed progressively as resonance energy transfer occurred between the polymerising fluorescein and rhodamine-labelled subunits See text

both fluorescein and rhodamine emissions) The sample was excited at 480 nm instead of at the excitation maximum of 496 nm to minimise the direct excitation of rhodamine Before polymerisation (Fig 1, zero time) a simple fluorescein emission spectrum was observed There was no energy transfer and thus no rhodamine emission Later (Fig 1, 2 min and later) as subunits separately labelled with F and R were brought together, resonance transfer occurred and the characteristic emission peak of rhodamine progressively increased Simultaneously, since resonance transfer and emission compete for the excited state, a decline in fluorescein emission was observed When F-T alone (no R-T present) were polymerised, no decrease in fluorescein emission occurred The depopulation of the fluorescein excited state by energy transfer to rhodamine is also reflected in a decrease in the excited state lifetime Fluorescent lifetime measurements[14] showed a decrease from 5 15 ns for MT assembled from F-T dimers alone to 3 64 ns for maximally (>70%) polymerised MTs assembled from the F-T plus R-T mixture From these data a mean distance between chromophores of 44 Å was calculated[7] The same distance was obtained by calculation from the energy transfer spectrum of maximally polymerised MT obtained in Fig 1, and is consistent with the known geometry of MTs (Fig 2)

Energy transfer did not occur when depolymerised F- and R-labelled subunits were incubated under conditions in which polymerisation did not occur (at 4 °C, or in the presence of 4 mM calcium chloride, or in the absence of GTP) But we observed interactions between subunits in the presence of colchicine, a plant alkaloid that binds with tubulin subunits and is thought to prevent their association into microtubules A tenfold molar excess of colchicine slowed markedly the increase in the light scattering None the less, in the presence of colchicine resonance transfer increased progressively with time and to nearly the same degree as in the absence of the alkaloid This indicates that most of the MT subunits are probably associated into small aggregates These aggregates seem to be readily dissociable the addition of unlabelled tubulin to the colchicine mixture, or simple dilution, led to a rapid fall in energy transfer In contrast, neither unlabelled tubulin nor dilution altered the energy transfer of polymerised MT Thus, the effect of colchicine on the interaction of subunits was different from the effects of cold or calcium which prevent polymerisation and the development of energy transfer and light scattering

Preliminary experiments have also demonstrated interactions of MT and/or tubulin with isolated cytoplasmic membranes Cytoplasmic membranes were isolated from rabbit polymorphonuclear leukocytes as previously described[8] and incubated with FITC at approximately 25 µg FITC per 100 µg membrane protein for 10 min at 4 °C The labelled membranes were then washed free of unreacted FITC by recentrifugation through a discontinuous sucrose gradient R-T was prepared as before and mixed with the labelled membrane At 4 °C virtually no energy transfer took place between F-labelled membranes and R-labelled tubulin At 37 °C polymerisation of R-T occurred, and resonance energy transfer between F-membranes and R-tubulin developed in parallel with the increase in light scatter This transfer was not diminished by the addition of unlabelled tubulin subsequent to polymerisation Similar experiments using rhodamine-labelled bovine serum albumin and fluorescein-labelled membranes did not reveal energy transfer at any temperature These experiments suggest a specific association of polymerised MT with membrane Energy transfer between R-T and F-membranes increased progressively with time in the presence of colchicine, just as it did between R-T and F-T with colchicine Further, addition of unlabelled tubulin to the membrane–tubulin complex formed in the presence of colchicine (10^{-4} M) rapidly reduced the resonance transfer Thus, in the presence of colchicine the association of tubulin with membranes, like the association of tubulin with tubulin seems readily reversible, and is distinct from the association formed in the absence of the alkaloid The high

Fig. 2 Schematic diagram of microtubule and disposition of constituent fluorescent labelled subunits The diagrammatic tubule was generated using the known geometry of MTs[15] and distributing tubulin dimers labelled with fluorescein (F), rhodamine (R) and unlabelled dimers (N) in the tubule according to a list of random numbers The proportions of F, R and N were calculated from the D/P ratios of F-T (0 15) and R-T (0 46) measured in a maximally (> 70%) polymerised suspension of MT, assuming that the association of dye molecules with tubulin follows a Poisson distribution[16] In this mixture, the distance between F and R calculated from resonance transfer as described in the text is approximately 40 Å This is consistent with the dimensions of the MT as shown, which is made up of protein dimers with a cross-sectional diameter of roughly 40 Å This correspondence suggests that resonance transfer occurs only between immediately adjacent subunits

efficiency of energy transfer observed (> 50%) indicates considerable interaction of the tubulin and membrane, and suggests that some labelled constituent of the membrane preparation could serve as a nucleation centre for MT polymerisation

In summary the use of long range non-radiative energy transfer provides a new approach to the study of MY polymerisation This method gives information on the geometry and interactions of subunits and of interactions between MTs and other cell constituents It has been applied to demonstrate loosely associated tubulin aggregates formed in the presence of colchicine, and binding of microtubules to isolated membranes, neither of which has been observed with conventional techniques These experiments are now being extended to explore the specificity and number of membrane binding sites for tubulin under different physiological conditions. The approach should prove useful in the study of other polymerisations (for example, microfilaments), particularly of their interactions in mixed systems containing membranes

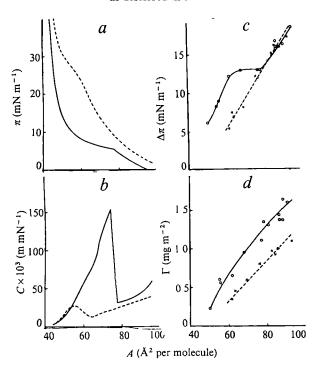
Lateral compressibility and penetration into phospholipid monolayers and bilayer membranes

THE phospholipid bilayer[1] in certain biological membranes 1 maintained so that the range of temperature over which the gel to-liquid crystal transition occurs includes the environmenta temperature[2] As a result, clusters of phospholipid molecules u crystalline and liquid-crystalline states[1] coexist in the membran and the isothermal lateral compressibility of the membran lipids is enhanced[3] Any increase in compressibility shoul facilitate insertion of foreign molecules into the bilayer thereb affecting transport across the membrane Indeed, there 1 evidence that transport of ions[4,5] and sugars[3], and penetratio of an enzyme[6] is increased when the chain-melting transition c the lipids occurs The lateral compressibility of phospholipi bilayers has not been measured, however, and there is no direc evidence for an increase in compressibility at the point wher the gel-to-liquid crystal phase transition occurs In order t measure lateral compressibility, compression solely in the plan of the bilayer is required Such directed compression of bilayer will be difficult but it can be readily achieved with monolayers a the air–water interface Since the molecular packing in suc monolayers of phospholipids is equivalent to that in bilayer dispersed in excess water[1,7], this model system is particularl convenient for exploring the role of lateral compressibility Here we show (1) how the compressibility of lecithin mono layers varies with packing density and changes at the chain melting transition, and (2) how penetration of a hydrophobi protein is dependent on the compressibility

The procedures used to obtain the surface pressure (π) molecular area (A) isotherms for chromatographically pur 1,2-dipalmitoyl phosphatidylcholine (lecithin) have bee described before[7,8] The preparation and adsorption characteri tics of 1-[14]C-acetyl-β-casein A have also been published[9,10] th protein is very hydrophobic and its behaviour at the air–wate interface is like that of proteins which are associated with lipid *in vivo* and quite different from that of highly water-solubl globular proteins The penetration experiments were performe at constant surface area by maintaining the lecithin monolaye at an initial A with a barrier and injecting the protein into th substrate The initial substrate concentration of protein wa 1 × 10⁻⁴ g per 100 ml and the changes in π and surface concen tration of protein (Γ) were monitored during adsorption with Wilhelmy plate and gas-flow counter[11], respectively

Figure 1a shows the π–A curves for dipalmitoyl lecithi spread at 20 °C and 30 °C on to a phosphate buffer (I = 0 1 pH 7), the isotherms are similar to those for a 0 1 M NaC substrate[7] The inflection at π = 5 6 mN m⁻¹ and A = 77 Å² pe molecule (this point is difficult to reproduce and is sensitive t the rate of compression) is a result of the onset of two-dimen sional crystallisation[1,7] and over the region where the π–A curv is more-or-less horizontal the monolayer consists of a mixture o crystalline and liquid-crystalline domains Because the transi tion is equivalent to that occurring in bilayers, the critica temperature[1,7] for the monolayer transition is the same as th bilayer transition temperature (41 °C) The monolayer phas transition is probably best described as "diffuse" first order[12,1] because the compressibility (C = −1/A(δA/δπ)_T) plotte as a function of A (Fig 1b) does not become infinite at the onse of condensation[17] The form of the plot of C against A is th

ame as that generally found for monolayers which undergo the phase transition[17] The dependence of C on the phase of the ipalmitoyl lecithin monolayer is similar to that generally found[16] for lipids thus C increases by a factor of about 5–0 15 1 mN^{-1} on moving from the liquid-expanded (for a definition of terms see ref 18) to the transition (intermediate[18]) region In the rystalline (condensed) region $C \sim 0\,004$ m mN^{-1}


The magnitude of C is directly related to fluctuations in the total number of particles in the system[19] The high compressibility at the phase transition results from large density fluctuations in this region Because of such fluctuations in surface density π will also fluctuate and Blank[20] has shown that the instantaneous surface pressure is related to the mean value $\langle \pi \rangle$ by equation (1)

$$\pi \simeq \langle \pi \rangle [1 \pm (kTC/A)^{\frac{1}{2}}] \qquad (1)$$

As a consequence of the enhanced lateral compressibility in the transition region, when $\langle \pi \rangle \sim 20$ mN m^{-1} (which is characteristic of phospholipid bilayers[1]) π can fluctuate locally between 3 and 37 mN m^{-1} Fluctuations which give rise to a low π are equivalent to hole formation in the monolayer, such holes lead to enhanced permeation of small molecules[20,21]

High values of C also enhance penetration of large molecules such as proteins which compress the lipid to clear a space (X) for themselves In this case, penetration is opposed by an activation energy barrier $E = \langle \pi \rangle X$ Penetration continues with increasing $\langle \pi \rangle$ (Fig 1c) until E becomes too large, generally this point is reached and penetration ceases when $\langle \pi \rangle \sim 30$ nN m^{-1} (refs 22, 23) The area which can be cleared by compression of the lipid for a given increase in $\langle \pi \rangle$ is obviously proportional to C As a result it is to be expected that protein

penetration is enhanced when C is high That this is indeed the case can be seen from Fig 1d It is apparent that Γ for β-casein is higher at 20 °C than at 30 °C (Γ for β-casein at the air–water interface is independent of temperature over this range) because the phase transition is prominent at 20 °C and C is much greater (Fig 1b) We could not detect any differences in the rate of increase of Γ at the two temperatures

The increase in π on penetration of protein (Fig 1c) arises from the increase in packing density in the interface The molecular packing in the mixed film can be described by a model[9,24] in which it is assumed that the protein penetrates and condenses the lecithin molecules to give a mosaic structure The detailed packing of the dipalmitoyl lecithin molecules in the mixed film cannot be determined from the present data The initial physical state of the lecithin monolayer is important through its effect on C, for example the initially condensed monolayers formed by higher lecithin homologues[7] give rise to a small degree of penetration with β-casein[9,24] Consistent with this, the dashed lines in Fig 1c and d extrapolate to zero $\Delta\pi$ and Γ when $A \sim 47$ Å^2 per molecule, at this point the phospholipid molecules are closely packed and there is no free space in the film into which protein molecules can penetrate The presence of cholesterol which leads to the formation of condensed monolayers with lecithin[1] also reduces C and should therefore inhibit protein penetration (compare ref 25)

We can conclude that the lateral compressibility of phospholipid monolayers and bilayers is an important parameter in determining their permeability If in vivo a biological membrane is maintained so that the phospholipid bilayer contains bo h crystalline and liquid-crystalline regions in equilibrium then the resultant enhancement of lateral compressibility facilitates insertion of hydrophobic proteins As a result the concentration of such proteins inside the membrane can be increased and if they are functional in transport, then the membrane permeability rises (compare ref 3) Besides processes such as membrane transport and assembly (biogenesis), the high lateral compressibility arising when a biological membrane is maintained in the range of the gel-to-liquid crystal transition may be of fundamental importance for membrane processes in general A phospholipid monolayer at the air–water interface is a particularly convenient model for quantitative studies of the role of lateral compressibility The elucidation of the exact role of high lipid compressibility in membrane biology warrants a systematic investigation

Amino acid transport defect in glutathione-deficient sheep erythrocytes

THE tripeptide, reduced glutathione (GSH), is present in high concentration in mammalian red blood cells, where its major role is thought to be the protection of the cell against oxidative damage Congenital red cell GSH deficiency has been reported in man, and attributed to a decreased activity of either of the two enzymes (γ glutamyl cysteine synthetase (GCS) or GSH synthetase (GSHS)) involved in GSH biosynthesis[1] Such GSH-deficient red cells have a markedly diminished lifespan, and an increased susceptibility to the haemolytic action of oxidant drugs[1]

Sheep with low concentrations of red cell GSH were first found by Smith and Osburn[2] and subsequent investigations have revealed at least two distinct types of congenital sheep red cell GSH deficiency[3-5] The first is associated with a diminished activity of the first enzyme of GSH biosynthesis (GCS) and is found in Tasmanian Merino sheep ("Merino-type")[6] The second, found in Finnish Landrace sheep ("Finn-type"), is characterised by normal activities of both GCS and GSHS[6], and results in a shortened red cell lifespan[7], and an increased susceptibility to kale poisoning[8] Significantly, in the latter, but not in the former type of deficiency, the red cells contain high concentrations of certain amino acids, particularly lysine and ornithine[5] It is therefore possible that the low concentrations of GSH in these animals may result from a reduced amino acid permeability limiting the availability of GSH precursors, or from a direct effect of the accumulated amino acids on the enzymes of GSH biosynthesis

To test the first possibility we have measured the permeability of normal (high GSH) and GSH-deficient (low GSH) Finn red cells to the GSH-precursor amino acids (cysteine, glutamate, glycine) and compared the results obtained with those for high and low GSH Merino cells The data are presented in Table 1 together with values for glutamine, α-amino-n-butyric acid (αAB), cystine and lysine uptake by high and low GSH Finn red cells The uptake of cysteine was rapid in Finn red cells, and sixfold greater in high GSH cells than in low GSH ones In contrast, the uptake of cysteine by high and low GSH Merino red cells was the same, and not significantly different from that found in high GSH Finn cells As with cysteine, glycine uptake was significantly lower in low GSH Finn red cells, although both the absolute fluxes and the difference between the GSH types were smaller There was no significant difference in glycine permeability between high and low GSH Merino red cells Attempts to demonstrate glutamate uptake by sheep red cells gave very low values, which were not linear with time The impermeability of sheep red cells to glutamate is consistent with observations on human red cells[9] Glutamine may act as a GSH precursor[10] and measurements of glutamine uptake showed fluxes of the same order as for glycine, but with no significant difference between Finn GSH types

In certain reactions (including that catalysed by GCS), αAB can substitute for cysteine[11,12] and may therefore provide a convenient alternative to cysteine for uptake studies. The

Table 1 GSH levels and amino acid uptake rates in red cells from high and low GSH Finnish Landrace and Tasmanian Merino Sheep

	High GSH Finn	Low GSH Finn	Significance level for difference (P)
No of animals	5	5

Data presented as mean ±s e m
NS, not significant
Washed sheep red cells were incubated at 10% haematocrit in a medium containing (mM) NaCl 135, KCl 5, Tris-HCl(pH 7 1 at 37 °C) 15, $MgCl_2$ 3 1, EDTA 0 1, amino acid 0 2 (containing ^{14}C-amino acid at 0 2 µCi ml^{-1}) Since cysteine oxidises rapidly in solution at neutral pH, cysteine uptake was measured in the presence of 10 mM dithiothreitol Control experiments showed no effect of 10 mM dithiothreitol on αAB influx or efflux At fixed time interval (10–30 min for Gly, αAB, Lys, Cys/2, 30–90 min for Cys, Gln Glu), aliquots (1 ml) were taken and the cells washed four times in ten volumes of a medium containing (mM) $MgCl_2$ 106, Tris-HCl (pH 7 4 at 4 °C) 10, by centrifugation (10 s, 10,000g) in an Eppendorf 3200 microcentrifuge Finally, the packed cells were lysed in 0 5% Triton X-100 in water (0 5 ml), 33% trichloracetic acid added (0 5 ml) and the precipitate removed by centrifugation An aliquot of supernatant (0 9 ml) was placed into Bray's solution[14] (10 ml and counted in a β scintillation spectrometer with quench correction

uptake of this amino acid by Finn red cells was therefore measured, and found to be rapid, with the flux in high GSH cells some tenfold greater than that encountered in low GSH cells In contrast to the situation with cysteine and αAB, cystine (the oxidised form of cysteine) showed a slow rate of uptake, with no significant difference between high and low GSH Finn cells The uptake of lysine, which is found at concentrations of up to 20 mmol per litre packed cells in low GSH Finn red cells was measured in high and low GSH Finn cells High GSH cells showed a threefold greater lysine permeability than low GSH cells

The above results show that differences in amino acid transport, particularly for cysteine, αAB and lysine exist between high and low GSH Finn red cells In contrast to glutamate and glycine, the concentration of cysteine in sheep red cells is very low (13 µmol per litre packed cells)[13] Thus a diminished cysteine availability may be responsible for the low concentrations of GSH in low GSH Finns

The reduced amino acid transport in low GSH Finn red cells is not a direct consequence of a low intracellular GSH concentration, since low GSH Merino red cells show normal amino acid uptake values Further experiments were designed to determine whether the diminished amino acid uptake by low GSH Finn red cells resulted from a membrane transport defect or whether it was a function of the high lysine and ornithine content of these cells Uptake of αAB (0 2 mM) by high GSH Finn red cells was unaffected by the presence of extracellular lysine or ornithine (10 mM) Similarly, αAB efflux from the same cells (preloaded by incubation in the

157

esence of 1 mM αAB for 2 h at 37 °C) was unaffected by
tracellular lysine or ornithine at a concentration of 5 mM
contrast, 10 mM cysteine inhibited αAB uptake by 50%
d stimulated αAB efflux by 30% under equivalent conditions
inally, high GSH Finn red cells were preloaded with lysine
y incubation in the presence of 10 mM lysine for 20 h at
) °C Uptake of αAB (0 2 mM) by these cells (intracellular
sine concentration 3 0 mmol per litre packed cells) was identical
that of control high GSH cells which had been incubated
r the same length of time in the absence of lysine (intra-
ellular lysine concentration 0 1 mmol per litre packed cells)

We therefore conclude that the diminished amino acid
ptake of low GSH Finn red cells represents a membrane
transport defect which is not a consequence of the low GSH
r elevated lysine and ornithine concentrations in these cells
: further seems likely that diminished availability of cysteine
responsible for the low concentrations of red cell GSH in
iese animals, and that the accumulation of lysine and orni-
iine is a further reflection of reduced amino acid transport

New type of infectious complex of *E. coli* RNA phage

REPARATIONS of the three components of RNA phage—RNA,
oat protein and maturation protein (A protein)—have been
ised in several attempts to reconstitute the particles *in vitro*[1-7]
Particles recovered so far have been similar to authentic particles
with respect to S value, morphology and other properties We
iave now reconstituted a complex, by mixing RNA and A
protein only, which can infect *Escherichia coli* regardless of its
small S value, 28S

Preparation of phage RNA and A protein, and conditions for
reconstitution are described in the legends to Table 1 and
Fig 1 Polyacrylamide gel electrophoresis showed that A
protein was not contaminated by coat protein Infectivity of
MS2 RNA-MS2 A protein complex, measured as described in
he legend to Table 1, was detected only when RNA and A
protein were mixed, and it seemed to increase when the mixture
was dialysed The greatest efficiency of infectivity observed was
approximately 1 4 × 10⁻⁵ plaque-forming units (PFUs) per
RNA strand (after dialysis) Sucrose gradient centrifugation
of the mixture gave peaks of absorbance and infectivity corres-
ponding to those of RNA (Fig 1a and b) This suggests that the
major component of the reconstituted complex is a single
molecule of RNA, and that one or a few molecules of A protein
play some roles in infecting intact host cells

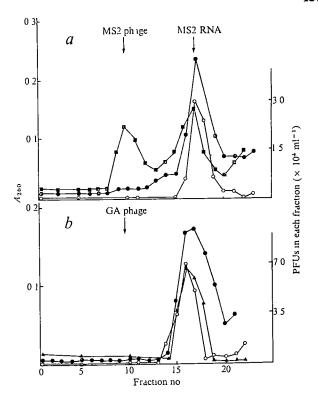
By assaying infectivity of the complex on *E coli* K12 Hfr Q13,
F⁺ A/λ, F⁻ W3110 and C15 (a derivative of A/λ which is
resistant to MS2 and GA phages), we found that the host range


Fig 1 Formation of RNA–A protein complex P hage RNA
and phage protein were isolated from purified phage by the
SDS-phenol method[12] The isolated RNA was purified further by
sucrose gradient centrifugation and ethanol precipitation The
phage mixed protein (coat protein and A protein) was recovered
from phenol layer by the method of Hung *et al*[4], and dissolved
in 5 M guanidine-HCl, plus 0 05 M mercaptoethanol in 0 1 M
Tris-HCl buffer (pH 7 2) A protein was isolated from MS2
phage and GA phage by the method of Osborn *et al*[13] A protein
was dissolved in 5 M guanidine-HCl, plus 0 05 M mercapto-
ethanol in 0 1 M Tris-HCl buffer (pH 7 2) A 1-ml sample of
reaction mixture contained the following components, 5 μg of
MS2 (a) or GA (b) A protein, 100 μg of MS2 (a) or GA (b) RNA
(dissolved in 0 01 M Tris-HCl (pH 7 2), 0 005 M MgCl₂), 5 mmol
of guanidine-HCl, and 50 μl of mercaptoethanol in 0 1 M
Tris-HCl buffer (pH 7 2), and 200 μg of phage mixed protein if
used After dialysis as in Table 1, the reaction mixture was
centrifuged in a 5 -20% (w/v) linear sucrose density gradient at
1 °C for 4 7 h (25,000 r p m) in a Spinco SW 27 rotor Fractions
were collected from the bottom of the tube and analysed for
infectivity and absorbancy at 260 nm *a* ■, MS2 RNA+MS2
A protein + MS2 mixed protein, ●, absorbance of MS2
RNA–MS2 A protein complex, ○, infectivity of MS2 RNA–
MS2 A protein complex, *b* ●, absorbance of GA RNA–GA
A protein, ○, infectivity of GA RNA–GA A protein complex,
▲, absorbance of GA RNA

of the complex was identical to that of the phage from which
RNA and A protein were prepared

The sensitivity of the complex (MS2 RNA–MS2 A protein) to
anti-MS2 serum was tested and, unlike intact MS2 phage

Table 1 Infectivity of MS2 RNA–MS2 A protein complex

Assay mixture	PFU/RNA(μg)
RNA (before and after dialysis)	< 10²
A protein (before and after dialysis)	< 10²
RNA+A protein (before dialysis)	6 × 10⁴
RNA+A protein (after dialysis)	2 2 × 10⁵

A 1-ml sample of reaction mixture contained the following com-
ponents 5 μg of MS2 A protein, 50 μg of MS2 RNA (dissolved in
0 01 M Tris-HCl (pH 7 2), 0 005 M MgCl₂), 5 mmol guanidine HCl,
and 50 μl of mercaptoethanol in 0 1 M Tris-HCl buffer (pH 7 2)
If necessary the mixture was dialysed against Tris-acetate buffer
(0 1 M Tris-HCl (pH 7 2), 0 05 M KCl and 0 02 magnesium acetate)
in an ice bath for 18 h PFUs in the reaction mixture were assayed
on K12 F⁺ A/λ

Table 2 Sensitivity of MS2 RNA–MS2 A protein complex to anti-MS2 serum

	Control (PFU ml⁻¹)	+Anti-MS2 serum (PFU ml⁻¹)
Complex	3×10^5	5×10^5
MS2 phage	$1\,1 \times 10^7$	$4\,1 \times 10^4$

A 0 9-ml sample of a solution of MS2 RNA–MS2 A protein complex or MS2 phage suspension was mixed with 0 1 ml of anti-MS2 serum (K value = 5) and incubated at 37 °C for 10 min Remaining PFUs were assayed on K12 F⁺ A/λ In control, the complex or the phage was similarly treated in the absence of the serum

particles, the complex was resistant to the serum (Table 2)

The complex was much more sensitive to RNase, trypsin and Pronase than were intact phage particles (Table 3) The extreme sensitivity to RNase suggests that a naked RNA is a component of the complex

Analysis of the physical nature of the complex indicated that it was rather unstable Infectivity decreased to one-tenth after storage for 24 h at 4 °C Also heat pretreatment of the RNA destroyed infectivity Heating at 70 °C for 10 min in TM buffer (0 005 M MgCl₂ in 0 01 M Tris-HCl, pH 7 2) decreased the activity to one-eighth to one-twentieth, and at 100 °C to 10^{-4} or less

We conclude that a complex infectious to intact *E coli* cell

Table 3 RNase, trypsin and Pronase-sensitivity of MS2 RNA–MS2 A protein complex

	Survivors (PFU⁻¹ ml)

Retention of tumour-inducing capacity by adenovirus DNA after cleavage by restriction endonucleases

WE have previously reported that fragments of Simian aden virus SA7 DNA produced by physical breakage are oncogeni These fragments had an average molecular weight correspon ing to half-molecules ($11\,4 \times 10^6$) After separation of the hea and light molecular halves by density gradient centrifugatio we demonstrated that both half-molecule preparations reta the ability to initiate tumours in newborn hamsters We su gested that this may be caused by the presence of one or mo "oncogenic regions" in both molecular halves, or by rando breaks near the centre of the DNA which could result in single small oncogenic region, residing near the centre ar occurring with equal probability in either the heavy or ligl half-molecule preparation To clarify these results we ha studied the effect of several restriction endonucleases on tl oncogenic activity of SA7 DNA These enzymes produi defined fragments of the SA7 genome rather than the heter geneous populations produced by physical shear

DNA was extracted using a phenol method from virus th had been banded twice in CsCl gradients[2] Restriction end nucleases *Eco*RI and *Eco*RII were purified from *Escherich, coli* strain R204 and R15, respectively (Dr D Jackson) End nuclease *Hin*d was purified[4] from *Haemophilus influenz* (strain Rd, Dr H Smith) Endonuclease *Hga* was obtaine from *H gallinarum* (ATCC 14385) using a modification of tl method of Takanami and Kojo[5] Endonucleases *Hpa*I an *Hpa*II were purified[6] from *H parainfluenzae* (Dr J Setlow)

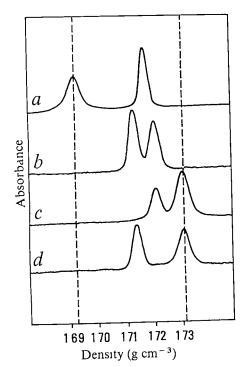
The number of fragments produced by the various enzym was found to vary from two to more than twenty (Table 1 *Eco*RI was found to make a single break in SA7 DNA Th result of analytical ultracentrifuge analysis (Fig 1) of DN/ hydrolysed by *Eco*RI revealed heavy and light fragment with buoyant densities corresponding to 61 1 and 53 9% guanine + cytosine (G+C) respectively, compared with intac SA7 DNA of 58% G+C Molecular weights for the heav and light fragments were calculated[7] and corresponded t 10 7 and 11 6×10⁶ dalton, respectively The alkaline sedimen tation coefficient for the mixed fragments ($S^0_{20,w} = 26\,2$) col responded to a single strand molecular weight of 5.5×10^5 These fragments are very similar to the heavy and light half molecule fragments produced by shear, except they represen homogeneous populations resulting from breakage of th DNA at a unique site


Fig 1 Model E ultracentrifuge scanner tracings of DNA preparations in CsCl-buoyant density experiments Two marker DNAs are shown *C perfringens* (ρ = 1 692) and *M lysodeikticus* (ρ = 1 731) The *Eco*RI fragments were separated on preparative NaI-EtBr gradients in a type 40 1 rotor (Beckman) by centrifugation for 100–200 h at 36,000 r p m The visible DNA bands were recovered and NaI was removed by dialysis Ethidium bromide was extracted from the dialysed DNA with isopropranol (three times) *a*, Intact SA7 DNA, ρ = 1 717, *b*, SA7 DNA cleaved by *Eco*RI, *c*, *Eco*RI heavy fragment, ρ = 1 720, *d*, *Eco*RI light fragment, ρ = 1 713

The mixture of fragments produced by each restriction enzyme was tested for oncogenicity by subcutaneous injection into newborn hamsters within 24 h of birth DNA (5 µg) was administered to each animal That cleaved by *Eco*RI or *Hpa*I retained the ability to initiate tumours (Table 1), whereas all the other preparations failed to yield tumours in the conditions tested Contamination by intact DNA could not account for tumour induction by either *Hpa*I or *Eco*RI fragments as gel electrophoresis data preclude contamination by more than 1%

Table 1 Tumour induction by SA7 DNA fragments

Enzyme	No of fragments	DNA/ animal	Tumour incidence	Length of test (d)
*Hin*d	20–25*	5 µg	0/34	365
Hga	20–25*	5 µg	0/56	85
*Hpa*I	7	5 µg	17/47	169
*Hpa*II	20–25*	5 µg	0/42	169
*Eco*RI	2	5 µg	7/35	282
*Eco*RI—Heavy		2 5 µg	4/59	120
*Eco*RI—Light		2 5 µg	0/77	120

SA7 DNA was digested with each enzyme for 1 h followed by addition of fresh enzyme and further incubation for 1–2 h In each case, the digestion products were examined using agarose or acrylamide-agarose gel electrophoresis to be certain that limit digests were obtained and that no detectable intact DNA remained (Approximately 0 01 µg SA7 DNA can be detected using EtBr staining Since 3–6 µg DNA was normally electrophoresed, intact DNA would represent at most less than 1% of the total) At the end of the digestion period, each preparation was deproteinised with phenol and dialysed against SSC (0 15 M NaCl, 0 15 M sodium citrate, pH 7 0)

* The number of fragments was estimated using electrophoretic separation 2 4% acrylamide-0 5% agarose gels More than twenty, but less than twenty-five bands could be distinguished for *Hin*d, *Hga*, and *Hpa*II

This amount of DNA per animal (0 05 µg) is insufficient to induce tumours at a frequency greater than 1% (J P B , N M , and L H , unpublished) When the heavy and light fragments produced by *Eco*RI were tested individually at a 2 5-µg dose, only the heavy fragments were oncogenic

This result demonstrates that the information required for tumour induction is probably unique and occurs only in the heavy half of the SA7 genome Thus, of the two possible explanations suggested for our previous experimental results with fragments produced by shear[1], the second alternative is more likely The existence of a single small oncogenic region of DNA near the centre of the SA7 molecule could therefore be found only in the heavy half-molecule after cleavage at a unique site by *Eco*RI, but may be found with roughly equal probability in both half-molecule preparations generated by random breaks resulting from shear (This is based on the fact that a break in the DNA molecule on the left or right side of such an oncogenic region would result in the activity being found in the light or heavy half-molecule respectively, whereas a break in the region itself may result in loss of activity) If this explanation is correct, we would expect to find the oncogenic activity near the central terminus of the *Eco*RI heavy half-molecule fragment We hope to resolve this in the near future, since we know that *Hpa*I produces six breaks in SA7 DNA, but only one of these is in the heavy *Eco*RI fragment of the molecule We are currently preparing and injecting these fragments to determine which *Hpa*I piece (or pieces) is responsible for the production of tumours by the *Hpa*I digest

Several authors have presented evidence that the transforming genes of human adenovirus type 2 may be near the left end of the Ad2 DNA molecule Gallimore *et al*[8] have analysed the DNA of rat cells transformed by Ad2 and found that some lines contain as little as 14% of the virus genome and that this region corresponds to the left end of the molecule Additionally, Graham *et al*[9] presented evidence that half-molecule fragments of human adenovirus type 5 DNA produced by shearing the DNA would transform primary rat cells in culture The transforming activity was found in the left or heavy (high G+C) half-molecule fraction They presented further evidence which suggested that the activity could be found in fragments as small as 10^6 dalton and may be localised in a region between 1 and 6% from the left end of the molecule Our results differ in the following ways First, we measured tumour induction *in vivo* rather than transformation *in vitro* Although we were able to obtain transformation *in vitro* with Ad5 DNA, we have not been able to induce tumours with either intact Ad5 DNA or *Eco*RI fragments (J P B ,* N M , and L H , unpublished) Second, we have not been able to induce tumours with SA7 fragments smaller than 5×10^6 dalton using either physically sheared material (ref 1 and J P B , N M , and L H , unpublished) or restriction enzyme fragments

Dark-repair of ultraviolet-induced pyrimidine dimers in the DNA of wild carrot protoplasts

GREEN plants receive greater exposure to solar ultraviolet radiation and their germ cells (pollen) have a significantly greater potential for acquiring ultraviolet-induced genetic damage than do those of most animals[1] Even though cells of the higher plants can photoreactivate ultraviolet damage (refs 2–5, and my unpublished data), the absence of dark-repair capability could be a significant disadvantage since some types of excisable ultraviolet-induced DNA damage are not photo-reactivable[6] The capability for dark repair would become even more important if there were an increase in the fluence of solar ultraviolet reaching the Earth's surface[7] Attempts to demonstrate excision of pyrimidine dimers in cells of *Nicotiana*, *Haplopappus*[4], *Ginkgo*[5] and *Chlamydomonas*[8] have all given negative results These data, taken with other assays for excision repair activity (unscheduled DNA synthesis[9], repair replication[10–12]) have been interpreted as indicating a general absence of such capability in plants[12] I have now found, however, that in cultured wild carrot cells, pyrimidine dimers can be excised in the dark and that the extent of dimer excision depends on the initial number of dimers induced by the ultraviolet dose After ultraviolet fluences of about 10 J m⁻², most of the dimers are excised within 24 h, but at fluences up to 30 J m⁻², about 25% remain unexcised in DNA At fluences above 100 J m⁻², dimer excision is almost completely eliminated, perhaps due to secondary effects of these very high ultraviolet doses.

The results of dimer analyses on wild carrot DNA are presented in Fig 1 and Table 1 The yield of dimers immediately after irradiation was linear for ultraviolet fluences of 0–450 J m⁻² and was equal to 0.002% radioactivity in thymine-containing dimers per radioactivity in thymine (X []T/T) per J m⁻² dose Thus the efficiency of thymine dimer formation was 35–40% that observed in bacteria[18] and mammalian cells[19]. This difference may be attributable to the shielding effect of cytoplasmic organelles in wild carrot protoplasts

The excision data fit a curve showing 100% dimer removal at lower ultraviolet doses Essentially complete excision of up to about 0 02% X []T/T occurred within 24 h, as reported in human cells for dimer levels up to about 0 01 % X []T/T (ref 20) My data for excision in wild carrot protoplasts are minimum values compared with those from work on animal cells, since in the latter case any dead cells are eliminated from the assay because they do not adhere to the surface of the culture dish[19]

Excision was almost completely eliminated at doses above 100 J m⁻², although a few dimers were excised even at the highest doses (Table 1) The 2% excision observed after 150–450 J m⁻² of ultraviolet amounted to about 10⁵ excised dimers per cell

Alkaline sucrose gradient analysis revealed about 0 2 single-strand gaps per 10⁸ daltons of DNA appearing immediately after 35 J m⁻² 254-nm irradiation of wild carrot protoplasts (my unpublished data) This implies about 10⁴ dimer-specific endonuclease molecules per cell, if the number of gaps corresponds to the average number of repair molecules Similar data have been obtained for mammalian cells[23] A fluence of 42 J m⁻² induced approximately 8 4×10⁵ pyrimidine dimers per cell (These data are based on a 2C nuclear DNA content of 2 1×10⁻¹² g per cell[24] and on an approximation of the relative frequencies of C[]C, C[]T and T[]T dimers[8,18]) Since 58±15% of these lesions were excised in 24 h, the average rate of excision was 20,000–30,000 dimers h⁻¹, comparable with that estimated for excision repair in mammalian cells[20,23]

At 30–60 J m⁻² maximum excision (>70%) was observed after 24 or 40 h dark incubation Excision seemed to stop short of removal of all dimers, however, with no additional excision

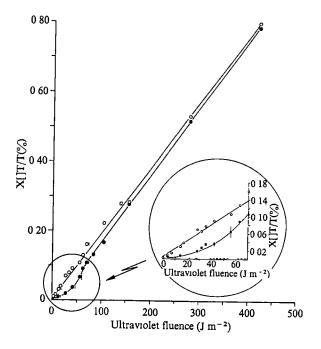
in the longer incubation All the dimers induced by 42 J m⁻ could be photoreactivated (Table 1), so that this apparent lim for excision was not an artefact of the dimer assay procedure Clayton *et al*[25] have shown that dimers are seemingly no excised from mitochondrial DNA in three mammalian ce


Fig. 1 Amount of thymine dimers as a function of ultraviolet fluence immediately after irradiation (○) and after ultraviolet followed by 24 h (●) or 40 h (■) dark incubation

Standard error bars shown around the mean of three to nine separate samples Dashed line indicates background dimer level in unirradiated samples The source and culture of wild carrot cells (*Daucus carota* L) have been described[13] Cellular DNA was labelled for 20–24 h by incorporation of methyl-³H-thymidine (17 Ci mmol⁻¹, Amersham/Searle) supplied at 5 µCi ml⁻¹ in the culture medium Fluorodeoxyuridine at 10⁻⁵ M was also included to inhibit the degradation of thymidine and to enhance the specific labelling of DNA (refs 21 and 22 and my unpublished data) Cell walls were digested and protoplasts isolated and counted as before[13] The specific radioactivity (acid-insoluble) was 4±1 c p m ⁻¹ per protoplast on average Protoplasts (1 0×10⁵–1 5×10⁵ml⁻¹) were irradiated as a disperse monolayer in Petri dishes through about a 2-mm depth of protoplast isolation medium[13] with agitation at room temperature The 2-mm thickness of medium transmits about 50% of the radiation at 254 nm, therefore a correction factor[14] of 0 70 was applied to the measured ultraviolet fluences Ultraviolet was delivered by a germicidal lamp (primarily 254 nm) at a fluence rate of 0 71 J m⁻² s⁻¹ as measured with a Jagger meter[15] The use of isolated protoplasts allowed reproducible, uniform ultraviolet exposures and quantitative induction of pyrimidine dimers During and after irradiation the protoplasts were handled only under non-photoreactivating illumination Thymine-containing dimers in samples of isolated[16] DNA were analysed by two-dimensional paper chromatography[17] For the lowest ultraviolet doses, two to three times more total radioactivity (in hydrolysed DNA) was applied to each chromatogram to allow recovery of a significant level of counts in the dimer region

lines that can excise dimers induced in nuclear DNA No dimer excision was detected in *Chlamydomonas* chloroplast DNA[8] If this were the case in my wild carrot protoplasts about 20% (the approximate proportion of organellar DNA in these cells) of the dimers would have remained after maximum excision This, in fact, is the approximate limit reached after ultraviolet fluences up to about 30 J m⁻² followed by 1 d dark incubation Experiments are now in progress to evaluate the

ossibility that pyrimidine dimers are not excised from organellar DNA in these cells

Although it is clear that pyrimidine dimers can be excised from the DNA of isolated protoplasts of cultured wild carrot cells, the distribution of this capacity among higher plants has yet to be determined Wild carrot protoplasts show a greatly reduced level of dimer excision when there are many dimers present (that is, initial levels greater than about 0 1% X[]T/T) This may explain previous failures to detect excision in tobacco (0 40% X[]T/T initial dimer level)[4], *Haplopappus* 1 12%)[4], *Ginkgo* (2 22%)[5] and *Chlamydomonas* nuclear equivalent to 0 33–0 66%)[8] and chloroplast DNAs (equivalent o 2 31%)[8] Other reports indicating an absence of excision epair activity in higher plant cells[9–12] must now be re-evaluated

I thank M L Yette for technical assistance, W L Carrier or advice on the dimer assays, and D Billen, W L Carrier and J D Regan for helpful comments on the manuscript This work was sponsored by the US Atomic Energy Commission under contract with the Union Carbide Corporation

Note added in proof Soifer and Cieminis have reported dimer excision in whole grass pea, *Lathyrus sativa* L) embryos[26]

Progressive decrease in protein synthesis accuracy induced by streptomycin in *Escherichia coli*

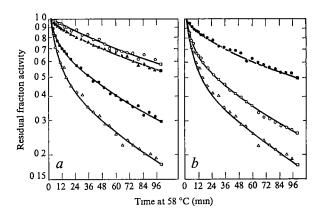
THE passage of genetic information from gene to polypeptide does not proceed with perfect fidelity[1–3], but it is not known what short and long-term cellular responses may be induced by decreases in the accuracy of protein synthesis Errors in gene expression may tend to increase their own rate of production[4], and thus could constitute a limiting instability of cellular life The synthesis of inaccurate RNA, RNA polymerases, tRNAs, tRNA modifying enzymes, tRNA charging enzymes and ribosomal proteins are potential pathways for the perpetuation or amplification of errors Such errors may be inducible *in vivo* by external chemical agents and may constitute an indirect pathway for mutagenesis[5–8] An enhanced rate of such errors may be the mechanism by which certain deleterious mutations exert their


Fig 1 Streptomycin-induced, time-dependent changes in the thermal stability of β-galactosidase A culture of a streptomycin-sensitive, lac permeaseless derivative of the K12 strain W1485 (called IH79) was grown at 37 °C in enriched medium (Luria broth and phosphate-buffered minimal A, as described in Miller[10], 1 1) to the mid-log phase and maintained there during the experiment by dilution into prewarmed medium Streptomycin (2 μg ml⁻¹) was added at generation time 0 in this experiment, and sample subcultures were withdrawn at the generation time indicated Each sample was induced by the addition of 1 0 mM isopropyl-β-D-thiogalactopyranoside for 30 min, thoroughly washed on a Millipore filter and resuspended in buffer A Reducing buffer[11] (0 2 ml ml⁻¹) was added to each sample, which was then lysed with chloroform (0 02 ml ml⁻¹) After 20 min of agitation the samples were centrifuged at 4,000 r p m for 20 min, and the remaining chloroform was removed from the supernatant by evaporation with agitation at 37 °C (Samples lysed in a pressure cell gave identical kinetics of β-gal thermal denaturation) Portions (1 ml) of each sample were incubated in plastic tubes at 58 °C (stable to within ±0 05 °C) for various times determinedby varying the starting time The incubation was stopped by agitating all the tubes in 19 °C water for 1 min The tubes were then allowed to stand at 37 °C for 90 min before assay for β-gal activity by hydrolysis of orthonitrophenol-β-D-galactopyranoside at 37 °C (ref 12) The residual fraction of enzymatic activity is plotted as a function of the time at 58 °C The zero and 100-min points are each the mean of five samples The generation time for each curve is the mid-point of the sample induction period calculated from the history of absorbance readings (650 nm) taken from the main culture Repeated runs with improved resolution showed that, with this procedure, the decay kinetics of β-gal from untreated cultures is first order to within 2–3% for 200 min after the first 5 min *a*, Curves for samples out to 7 5 generation, *b*, the two subsequent samples with the 7 5 generation curve repeated Samples taken at the indicated number of generations (doublings) *a*, ○, 0, ▲, 1, ●, 4 1, △, 7 5 *b*, △, 7 5, ○, 11, ●, 16

effects Here we report the results of experiments with *Eschenchia coli* designed to detect evidence of self amplification of errors in protein synthesis If such error feedback is quantitatively significant, a slight increase in the pre-existing error rate should be followed by a progressive decrease in the accuracy of protein synthesis While this process could lead to a new stable level and thus need not precipitate a catastrophic breakdown, some late effects should be observable if the mechanisms are at all as hypothesised

We have manipulated the error rate in protein synthesis by exposing the cells to low levels of streptomycin, an aminoglycoside antibiotic which increases the rate of ribosome-mediated misincorporation of amino acids[9] The fidelity of protein synthesis in a culture at a given time was assayed by measuring the thermal decay kinetics of the enzyme β-galactosidase (β-gal) produced by a freshly divided and induced subculture The thousandfold inducibility of this enzyme permits a reasonably sharp definition of the time at which the accuracy of protein synthesis is measured

In the basic experiment in this series, a culture was sampled just before and at various times after addition of streptomycin at concentrations in the range 0 5 to 5 μg ml⁻¹ Typical results are shown in Fig 1 Before addition of streptomycin the β-gal thermal denaturation curve had reasonably first-order characteristics, indicating a correspondingly homogeneous enzyme population After addition of the drug a progressively increasing fraction of the newly synthesised β-galactosidase molecules showed enhanced thermolability

Simultaneously with these changes in the β-gal thermolability pattern, the cultures themselves showed a delayed, progressively decreasing growth rate and a progressive increase in the production of multinucleate, filamentous cells Recovery of the culture, as measured by thermal decay of β-gal, (Fig 1b) was also accompanied by increased growth rate and disappearance of elongated cells These observations support the idea that the thermal decay assay detects a specific consequence of a general cell-wide effect

A series of experiments similar to that depicted in Fig 1 lead us to several additional observations and tentative conclusions concerning this effect (1) Both the maximum extent and speed of development of the effect showed nonlinear, direct dependence on the concentration of streptomycin (2) Maximum extent of the effect was correlated with the speed of its development The smaller the effect, the longer it takes to develop, it was maximal in 8 to 10 generations for high drug concentration (2–5 μg ml⁻¹) and in 14 to 17 generations for low concentration (about 1 μg ml⁻¹) These observations seem inconsistent with the idea that the simple replacement of some cell component by its post-treatment equivalent (without feedback) is responsible for the progressive nature of the effect (3) The effect was sensitive to the growth medium and growth history of the culture (4) Within a fourfold range of growth rates (produced by varying the growth medium), generation time and not the actual time seemed to determine the kinetics of development (5) With treatments mild enough to allow growth for a few generations after addition of streptomycin, the cultures ultimately recovered Recovery to normal growth rate and cell morphology was always correlated with decreased levels of thermolabile β-gal We have, however, never seen complete recovery in as many as 25 generations after addition of the drug

We do not know whether recovery was due to adaptation within the cells or to selection of some subtly resistant variants If a favoured phenotype was being selected, however, it must have been present initially at a concentration of about 1 in 10³ The recovered populations are not resistant to streptomycin at levels of 20 μg ml⁻¹ or higher, hence, classical streptomycin-resistant alleles of the *strA* locus are not involved

Since we observed increased heterogeneity of the thermal decay rates for β-gal, it seems unlikely that the change was due to some other factor produced by the treated cells, which persisted through our washing, resuspension and lysis proce-

dures and enhanced the thermolability of the enzyme To che this possibility, however, we mixed lysates from induced b untreated cells in various ratios with extracts from late, dru treated cultures that contained only basal levels of β-gal Tl thermolability of the enzyme was unaffected even when tl extract from treated cells was in fivefold excess and wh parallel induced samples of the treated cultures showed tl expected enhanced thermolability

A convincing test of the same question comes from a experiment designed to show whether the increased therm(ability is due to modification of the enzyme after synthes Since enzyme synthesised before addition of streptomyc remained unaffected (Fig 2), we tentatively attribute tl observed alteration of the protein to faulty protein synthesis

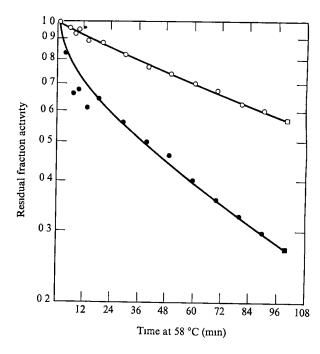
Another experiment showed that the growth of late strept(mycin-treated cultures was much more sensitive to temperatu than that of untreated cultures (Fig 3), implying that the molabile, but otherwise functional, protein required for growl is being produced in the treated cells


Fig. 2 Thermolability seems to be conferred at the time of protein synthesis Induced cells grown overnight to produce maximum levels of β-gal were deinduced by washing on a Millipore filter, and resuspended in medium containing streptomycin (2 μg ml⁻¹) A control sample was taken immediately (but not further induced) and the culture was allowed to grow for about 5 5 generations It was then divided into two samples (○ and ●), one of which (●) was induced for 30 min The procedures and conditions were otherwise as described in Fig 1 This figure shows the thermal decay curves resulting from these sample cultures The decay kinetics of the control sample were characteristic of untreated cultures and indistinguishable from the zero generation curve in Fig 1 and from curve ○ in this figure

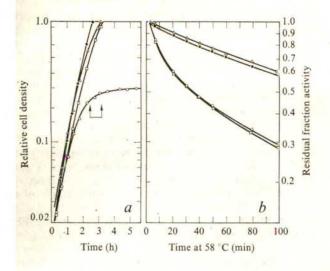
If we were observing a progressive breakdown in the accuracy of protein synthesis, it could have been due to causes other than error feedback a slow increase in the uptake of streptomycin, possibly the result of a feedback cycle directly affecting permeation, or of some process involving the metabolism or binding of the drug Indirect evidence that such effects are not implicated came from our examination of the immediate effect of high doses of streptomycin on the production of thermolabile β-gal (data not shown) Substantial fractions of thermolabile enzyme were produced as an immediate response


Fig. 3 Thermal sensitivity of the growth of treated cultures. Two freshly divided cultures of IH79, one with and one without streptomycin (2 µg ml^{-1}) were grown at 37 °C for four generations in exponential growth medium. At time zero, each culture was diluted into two flasks of the same medium, one held at 37 °C and the other at 42.5 °C. During subsequent incubation with agitation at these temperatures the growth of the cultures was measured by reading the absorbance at 650 nm. At the time indicated by the first arrow (*a*), samples were removed and induced at 37 °C. Induction was stopped at the time of the second arrow and the thermal degradation kinetics of the β-gal in each sample determined (*b*). Procedures and conditions were otherwise as described in the legend to Fig. 1. The strain IH79 normally grows well following a temperature upshift from 37 °C to 43 °C, but stops abruptly if shifted to 45 °C. ○, 42.5 °C, +streptomycin (2 µg ml^{-1}); △, 42.5 °C, −streptomycin; □, 37 °C, +streptomycin (2 µg ml^{-1}); ●, 37 °C, +streptomycin.

streptomycin and limitations of permeability of the drug revealed by pretreatment with EDTA–Tris[13]) played some role. The maximum immediate effect was, however, significantly less than the maximum late effect caused by streptomycin at µg ml^{-1}, and the high concentrations required ($\gtrsim$ 30 µg ml^{-1}) caused rapid cell killing. It therefore seems unlikely that the observed progressive effects of streptomycin resulted from changes in the intracellular concentration of active drug.

Mutations that confer resistance to high concentrations of streptomycin are mapped in the gene (*strA*) coding for a 30S subunit ribosomal protein (S12) and depress both the *in vitro* and *in vivo* error-producing effects of streptomycin[9]. Two resistant derivatives of IH79 and two independent resistant (*strA*) strains were found to have normal β-gal thermolability at concentrations of drug below 100 µg ml^{-1} but to produce a small amount of thermolabile enzyme (20% or less) when treated with 200 µg ml^{-1}. We conclude that the *strA* locus mediates the production by streptomycin of the progressive effect.

The results reported here suggest that error feedback in gene expression exists in *E. coli*, and constitutes a basis for further investigation of the stability of information transfer in gene expression.

This work was performed under the auspices of the US Atomic Energy Commission.

Structure of leghaemoglobin from lupin root nodules at 5 Å resolution

THE similarity in tertiary structure of mammalian haemoglobins[1-3] and myoglobins[4,5] and of haemoglobins from invertebrates[6,7] shown by X-ray analysis has been particularly important for our understanding of the biological evolution of these proteins. We have therefore studied the structure of leghaemoglobins—plant haemoglobins found in root nodules of leguminous plants—and compared the structures of seemingly unrelated, in terms of evolution, haemoglobins.

Leghaemoglobin from root nodules of the yellow lupin, *Lupinus luteus* L. is a monomeric haemoglobin of molecular weight about 16,000. The amino acid sequence for one component of leghaemoglobin from soya[8] suggested a correlation in structural organisation of the leghaemoglobin and other haemoglobins. The physiological role of leghaemoglobin is concerned in some way with the fixation of atmospheric nitrogen, formed symbiotically in root nodules of a higher plant by the bacteria *Rhizobium*.

Leghaemoglobin was extracted from root nodules by chromatography on Al_2O_3 and DEAE cellulose (*p*H 7.0), the protein being eluted by the ammonium acetate buffer. Crystals reached a size of 0.5 mm × 0.5 mm × 1 mm when grown in 28–33% saturated solutions of ammonium sulphate, buffered to *p*H 7.0 with 0.5 M ammonium acetate. The crystals are monoclinic (*a*=92.95 Å; *b*=38.31 Å; *c*=52.15 Å; γ=98° 50′; space

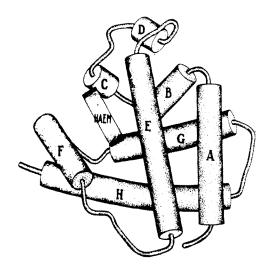
Fig. 1 The three-dimensional Fourier synthesis of electron density of leghaemoglobin.


Fig. 2 The model of the leghaemoglobin molecule at 5 Å resolution.

group B2) and the unit cell contains four molecules, one per asymmetric unit[9].

The structure was determined using four heavy atom derivatives containing HgI_4^{2-}, UO_2^{2+}, I_2 and 3-HgCl–pyridine, respectively. The heavy atom positions in HgI_4^{2-} and UO_2^{2+} derivatives were obtained by difference Patterson syntheses, the other two were resolved using difference Fourier syntheses and protein phases derived from HgI_4^{2-} and UO_2^{2+} derivatives. The heavy atom parameters, refined using a Muirhead program algorithm[10], are listed in Table 1.

The best Fourier synthesis[11] of protein electron density at 5 Å resolution was calculated using 830 independent terms with the mean figure of merit 0.85. This revealed unambiguously the course of the polypeptide chain and the position of the haem group, with some indication of its orientation (Fig. 1). A very close resemblance between the tertiary structure of the leghaemoglobin and known animal haemoglobins and myoglobins was clearly shown. A similar myoglobin fold to that reported for sperm whale myoglobin[4,5] was found and the electron density map clearly shows the eight straight 'α helices' A, B, ..., H (Kendrew's nomenclature[12]) joined by rather short irregular segments.

Estimation of the number of residues in α helices based on the lengths of straight segments of high density gives, for A, B, E and G helices in the leghaemoglobin, numbers close to those for sperm whale myoglobin (16, 16, 20 and 19 residues, respectively). The F helix seems to be longer (about 14 residues as against 9) and the H helix is slightly shorter (23

residues as against 26). Similar differences were observed in tl haemoglobin from the marine annelid worm, *Glycera c branchiata*[13].

The haem group seems to be in the form of an oblate ellipsoi and can be distinguished by the highest value in the electro density map. As in other haemoglobins the haem position between E and F helices with the narrow side facing the Cl region. The haem plane is roughly normal to the line joinir those parts of the E and F helices nearest to the haem.

The model of the leghaemoglobin molecule is shown in Fi 2. The similarity in tertiary structure between leghaemoglob and animal haemoglobins (myoglobins) seems to have son interesting implications for both evolutionary and function aspects. If this similarity arises from a common origin of tl animal and plant haemoglobins it would mean that haem globin was present in organisms which lived about 1.3×10^9– 1.5×10^9 yr ago and in which the animal and plant kingdon had their origin. The tertiary structures which have arise during evolution therefore seem to have been conserve in widely divergent branches.

This similarity, however, parallels with the very poor corr lation of the primary structures of haemoglobins (in all know haemoglobin sequences the true invariants are only 3 out of total of 140–150 residues). It suggests that all the elements three-dimensional structure which have traversed such var ability in molecular chemistry unchanged, are indispensab not only for the stability of the molecular architecture but als for fulfilling their diverse functions.

Corrigendum

obituary

Hugh Blackwell Evans, the Antarctic pioneer, died at the age of 100.

Hugh Evans was born at Alvington, Gloucestershire, in 1874 and died at Vermilion, Alberta on 5 February 1975. In 1896–7 he went in the *Edward* on a sealing expedition to Kerguelen, acting as assistant to Robert Hall, the ornithologist. In 1898–1900 he was a member of the *Southern Cross* Antarctic expedition under C. E. Borchgrevink, and was the last remaining member of the first ten men to winter on the Antarctic continent. In February 1900 he was one of the four men who achieved the "farthest south" on the Ross Ice Barrier. He was assistant to the zoologist, Nicolai Hanson, and when he died Evans took over his work, receiving the congratulations of Dr. Bowdler Sharpe. In 1901 he was offered a place on the staff of the National Antarctic Expedition, but being in Canada, farming, he was unable to accept. He spent the remainder of his working life as a Prairie farmer. In the last couple of years he published three articles on his Antarctic experiences in the *Polar Record*.

Hyman Levy, the distinguished mathematician, died on February 27 at the age of 85.

Born in Edinburgh, Professor Levy was educated at the Universities of Edinburgh, Oxford and Gottingen. After four years on the staff of the National Physical Research Laboratory, he joined the Department of Mathematics at Imperial College, London, in 1920 as assistant professor, becoming professor in 1923 and head of the department in 1946 before retiring in 1954. The governing body of the college elected him one of its members and appointed him Dean of the Royal College of Science (one of the constituent parts of Imperial College) in 1946, a post which he held for six years. In 1957, he was awarded a fellowship by the college. Levy's most significant contributions to mathematics, and the development of mathematical teaching, arose from his interests in numerical methods. This, and the related subject of statistics, remained his favourite field of mathematics throughout his life. He was also deeply interested in Marxism and was a member of a British delegation Communist Party which visited Russia in 1956. He investigated reports that Jewish writers, artists and intellectuals had been persecuted, and apalled by his findings, he wrote an exposure of such persecution in the Communist weekly *World News* in January, 1957. He later became very much disenamoured with Marxism.

announcements

Awards

J. E. Hyde and **S. E. Reynolds** have been awarded Harkness Fellowships of the Commonwealth Fund.

The Institute of Physics has made the following awards for various contributions: **Guthrie Medal and Prize** to **D. Tabor** (study of surfaces); **Glazebrook Medal and Prize** to **W. C. Marshall** (direction of the work of the Atomic Energy Authority, particularly the administration of Harwell); **Charles Chree Medal and Prize** to **R. Hide** (hydrodynamics of rotating fluids and their applications to the major planets); **Thomas Young Medal and Prize** to **D. J. Bradley** (laser physics, particularly the tunable dye laser); **Duddell Medal and Prize** to **E. Ruska** (electron microscopy and electron optics); **Charles Vernon Boys Prize** to **R. A. Stradling** (electronic properties of semiconducting and semimetallic solids, particularly quantum transport phenomena and magnetophonon spectroscopy); **Maxwell Medal and Prize** to **A. J. Leggett** (behaviour of condensed matter at very low temperatures, particularly the elucidation of the transition in liquid ³He);

Bragg Medal and Prize to **W. A. Coates** (design and execution of demonstrations for lectures at the Royal Institution).

Sir Brian Flowers, FRS, has been awarded the **Chevalier de la Legion d'Honneur** for contributions to greater cooperation in the field of science between France and Great Britain.

R. M. Shackleton, FRS, has been awarded the **Clough Medal** for contributions to Scottish geology.

J. McManus has been awarded the **Clough Award** for work on modern sediments, particularly those of the Tay estuary.

Appointments

J. M. Hirst has been appointed Director of the Long Ashton Research Station, and to a chair and the Headship of the Department of Agriculture and Horticulture in the University of Bristol.

R. E. Richards will be the next Vice-Chancellor of the University of Oxford.

T. S. West has been appointed Director of the Macaulay Institute for Soil Research, Aberdeen.

R. Miledi, FRS, has been appointed Foulerton Research Professor by the Royal Society. Miledi is professor of biophysics at University College, London, and will continue his studies on nerve–muscle interaction there.

A Royal Society Research Professorship has been awarded to **J. W. Cornforth, CBE, FRS.** Cornforth is a director of the Milstead Laboratory of chemical enzymology at Shell Research and will take up his new appointment in the school of molecular sciences at the University of Sussex.

Miscellaneous

Developing Countries. The International Union of Pure and Applied Physics is to support the expenses of three scientists from developing countries during the Fifth International Conference on Atomic Masses and Fundamental Constants (AMCO–5), to be held in Paris from June 2–6, 1975. Applications (with curriculum vitae

and a written recommendation) to: AMCO–5 Secretariat, Institut d'Electronique Fondamentale, Bât. 220 Université Paris-Sud F-91405, Orsay, France.

Achievement Award. Applications are invited for this award, made annually for a British or Commonwealth achievement in the field of scientific instruments—research, design, or new technique—by the Worshipful Company of Scientific Instrument Makers. Applications (by March 31) to: The Clerk, Worshipful Company of Scientific Instrument Makers, Alliance House, 12 Caxton Street, London SW1, UK.

Essay Competition. The Bertrand Russell Memorial Logic Conference is offering a prize of £200 for an essay that examines in detail some aspect of the relationship between mathematics and the development of social or economic conditions. To be of general interest to mathematicians and include a consideration of current mathematical practice. Deadline: February 1, 1976. Further details from: Dr A. Slomson, School of Mathematics, The University, Leeds LS2 9JT, UK.

Foulkes Foundation. Offers a number of fellowships to science or other suitable graduates who have recently received a Ph.D. or equivalent, and who wish to take a full second degree course in medicine. Also for recently qualified medical men and women wishing to take a scientific, technological or other suitable subject. Applications to: D. W. FitzSimons, Secretary, Foulkes Foundation Fellowship, The CIBA Foundation, 41 Portland Place, London W1N 4BN, UK.

International meeting

April 15–16, **Understanding Energy Systems**, London (R. A. Davies, Operational Research Society, Sixth Floor, Neville House, Waterloo Street, Birmingham B2 5TX, UK).

Person to Person

Weinberg's Differential Rule. Additional data required to test this rule. Would workers routinely ascertaining and blood-typing twins at birth please let me have the following data: among the pairs known to be DZ on basis of blood groups alone, how many are same-sexed, and how many are opposite-sexed? (Dr W. H. James, Galton Laboratory, Department of Human Genetics and Biometry, University College, London NW1 2HE, UK).

Enzymes. A summer course is being organised by the Massachusetts Institute of Technology on 'Enzymes and their Use in Analysis and Clinical Diagnosis', from June 23–27. Aims to develop ability to use enzymes as analytical reagents and measure their activities. Director of the Summer Session, Room E19-356, MIT, Cambridge, Massachusets 02139).

Echange de Maisons. Famille à Londres veut faire une échange de maisons avec famille française, août 9–16. Offert: maison de 4/5 chambres, 4 étages, tout ce qu'il faut pour bébés/enfants; location paisible dans un faubourg agréable, près de Greenwich, 20 minutes par le train au centre de Londres; visites interessantes aux environs. Demandé: maison, ville ou campagne, endroit agréable, Bretagne, Paris ou le nordouest, pour famille de 3 enfants (D. Davies, 32 St Margaret's Passage, London, S.E.13, UK).

Mitochondrial Structure and Function. This course, sponsored by the University Board of Studies in Biochemistry, will be held from April 7–10 and is designed for postgraduate or other qualified students in the London area. Consists of a series of lectures and practical demonstrations on mitochondrial bioenergetics. Registration fee: £10 (Dr P. J. Quinn, Department of Biochemistry, Chelsea College, Manresa Road, London SW3 6LX, UK).

House Exchange. House sought in English or Scottish fishing village, fortnight August, preferably near the spring tides. Offer in exchange our house in Stratford-upon-Avon. Family of two adults, two boys (both primary age), (R. C. Hardwick, 3 Mayfield Avenue, Stratford-upon-Avon, Warwickshire, CV37 6XB, UK).

There will be no charge for this service. Send items (not more than 60 words) to Robert Vickers at the London office. The section will include exchanges of accommodation, personal announcements, and scientific queries. We reserve the right to decline material submitted. No commercial transactions.

Why EPIC should not be squeezed out

DURING April the Science Research Council (SRC) will have to announce some sort of a decision on the future of proposals to build a new high energy physics facility at the Rutherford Laboratory. The machine under consideration is a 14 + 14 GeV electron–positron intersecting complex called EPIC, and would replace the 8 GeV proton accelerator NIMROD and the 5 GeV electron accelerator NINA—Britain's present major machines. Support for and participation in CERN at Geneva would not be affected by the EPIC proposals.

Almost all accelerators at present in operation generate particles which are fired at stationary targets. As a result of conservation of momentum and of special relativity, most of the energy is wasted in propelling the products of the collision forward. A 400 GeV proton, for instance, fired at a stationary proton provides only 28 GeV of useful energy to the centre-of-mass system. This somewhat underpublicised characteristic of conventional accelerators becomes even less attractive when electrons are the projectiles, and least attractive when electrons are fired at electrons (or positrons). To produce the same 28 GeV in the centre-of-mass system of a conventional electron–positron machine would require 800,000 GeV! Hence high energy physicists have increasingly turned to colliding-beam systems in which two beams of particles travel in opposite direction around a ring and collide at regular intervals. The observer in the laboratory frame of reference then gets full value for money.

But why study electron–positron interactions at all? The scientist not conversant with high energy physics might with some justification ask in an innocent sort of way whether everything hadn't already been thrown at everything else, judging by the great bulk of *Physical Review* and the extraordinary sameness of the titles of papers therein. Apparently not; the more work that is done on protons, for instance, the more complex their substructure seems to be and the more inappropriate proton–proton experiments become for the elucidation of that structure. "It is rather like throwing two watches at each other in order to discover what their internal layout is" was how one high energy physicist described such experiments. But if the trend is then towards using simple particles (electrons are still mercifully believed to be point-like) as probes of complex particles, much more has to be learned about the forces on these simple particles—notably electromagnetic and weak interactions.

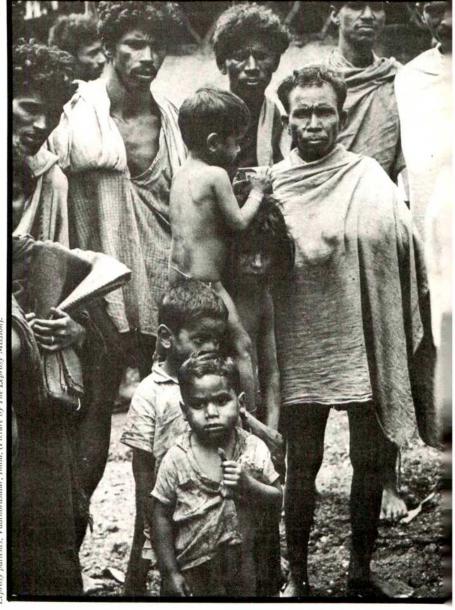
The scientific case for EPIC looks good, but scientific cases are hardly the only ingredient at present in decision making in science, particularly where the subject in question is indisputably a 'big science'. The Advisory Board for the Research Councils (ABRC) has recently warned that big science is in for a relatively lean time, and thus the EPIC proposal, which would involve 2,000 man years of staff effort and a capital investment of £25 million to get into operation by 1980, looks particularly vulnerable.

It would obviously make a positive decision much easier if the international dimension were more clearly known. Are there prospects for bilateral or multilateral deals involving cost sharing? It is difficult to assess this at the moment, as other countries, particularly Germany, are also interested in EPIC-type machines, and it is probable that if Britain says no, Germany will build.

The omens are not good. EPIC will be coming up for consideration at the same time as the Northern Hemisphere Observatory proposal; more and more often those involved in big science will find themselves in competition for limited money. It would be easy, and wrong, for the ABRC (which is likely to make the decision) to adopt a Buggins' turn attitude and let the astronomers have their observatory at the expense of EPIC because the astronomers didn't get their last big request, the Mark VA radiotelescope.

It would be equally wrong for the decision to be made in an atmosphere of antipathy to big science in which requests for large sums of money were rejected on some sort of principle that very fine work is being done by people who do not make inordinate demands on resources and it is time to cut the big boys down to size.

Finally, it would be wrong to turn down EPIC on the basis that high energy physicists are an isolated elitist bunch of people who have had a good run for their money, who don't do anything that anyone else can understand and who aren't within sight of any success which is going to provide benefits for the world-at-large. There is some force to these criticisms; high energy physicists are increasingly aware of the alienation between themselves and other scientists and of their general failure to have communicated the intellectual excitement of the subject to a broad audience. Even so, it would be grasping at a convenient but not relevant excuse to make a major decision for this reason.

Morale in the scientific community has never been lower, as job prospects diminish, governmental interest in science touches rock bottom and students turn away from science as a career. A very necessary step to restore some confidence is investment in large-scale long-term projects, and EPIC is just such a one. High energy physics shows strong signs of moving into a period of great excitement, and Britain's previous investments mean that there is much expertise in the field. Support for EPIC would show in an unambiguous way that those who make decisions in British science are aware of the need to restore confidence in pure science as an intellectual exercise, and are prepared to fight for it in high places. □


Leprosy: is the strategy wrong?

Authoritative opinion claims that there has been a failure to provide treatment for most of the world leprosy patients and to control the spread of the disease. But sulphones provide a cheap and practical form of treatment and also prevent transmission of leprosy, writes C. L. Crawford, of the Department of Anatomy and Embryology, University College, London.

IN 1873 the Norwegian Armaeur Hansen found bacteria in the tissues of leprosy patients and thus established the infectious nature of the disease. Today the World Health Organisation (WHO) estimates there are 10.8 million people with the disease, of whom only about 18% are receiving any treatment. Although information is limited it also concludes (*Bull. Wld. Hlth. Org.,* **46,** 523; 1972) that there has not been any improvement in controlling the spread of the disease over the past five years. The British Leprosy Relief Association (LEPRA) claim that there are as many as 20 million patients. Browne and Davey, two of the most experienced leprologists, (writing this year in *Leprosy Review*), conclude that existing methods have failed to reduce the incidence of the disease, and Ambrose *Nature,* **248,** 370; 1974) states that leprosy is increasing in South Asia.

Leprologists stress the unknown facts about the disease; the bacteria cannot be cultivated so a vaccine cannot be developed, and the mode of transmission and the incubation period are unknown. Faced with this lack of knowledge and the pessimism of authoritative opinion, the outlook seems hopeless both for success in preventing the spread of the disease and for the patient's chances of obtaining treatment. But the efficacy of the sulphone in providing a cheap and practical form of treatment and in prevention has been grossly neglected.

The difficulty in culturing *Mycobacterium leprae* could, in fact, be seen as a potential advantage in an attack on the disease. *Mycobacterium leprae* is confined to humans and must therefore exist outside the body only for very short periods. There is no known animal reservoir of infection or vector to spread the disease and transmission takes place only between humans. Probably only a proportion of leprosy patients are responsible for

Leprosy patients, Vadhiorasalur, India. (Picture by The Leprosy Mission).

transmitting the disease. This multi-bacillary or lepromatous group may be as low as 10% in some parts of the world and constitutes the reservoir of infection. Also only one in ten of the exposed population, at the most, acquire the disease even in the absence of control measures. If transmission could be interrupted in susceptible people, the disease would decline, as indeed it did in Norway in the last century by a policy of segregation. Also, once eradicated from any country it has never returned. A vaccine is not essential for eradication as the disease has already disappeared from many countries. The transmission of yaws has been successfully interrupted without the bacteria being cultivated or a vaccine developed, by treating patients with penicillin.

The sulphones are the main drugs used in the treatment of leprosy. The experimental multiplication of *M. leprae* in mice is inhibited if *M. leprae* from patients who have received more

than three months of sulphone treatment are injected, suggesting that such bacteria are no longer viable. It may thus be that patients with leprosy are no longer infectious after a few months of treatment, and sulphone may have an important role in preventing the spread of the disease as well as in treatment. Sulphones have been used for the past 25 years and it is essential to determine if they have had an effect in preventing transmission of leprosy.

Any successful preventative measure against leprosy will be shown by a fall in the number of new cases or in the incidence rate; the total number of cases (or 'prevalence' rate) will change much more slowly, because of the inclusion of patients who are already crippled. If the majority are of this type, the prevalence may hardly change at all over a period of years even though transmission may have been completely interrupted, because leprosy patients can live a long time

The life expectancy of untreated lepromatous leprosy in Hansen's time was about 10 years; now, with sulphones, it is the same as in the general population. Thus, the 'prevalence' may actually rise in a community treated with sulphones. It is therefore very surprising that the WHO should attempt to draw conclusions about the spread of the disease from the figure of 10.8 million, which is a prevalence estimate. No attempt has been made to obtain information about incidence rates, and even the estimate of the total number of cases is based on very questionable assumptions. Of the 10.8 million, 2.5 million are actually registered; 0.5 million of these are cured or arrested. In each country, to make allowance for unknown cases, a percentage of the registered cases was calculated depending on the efficiency of case finding. This varied between 25% and 300% of the registered cases. This total was added to the 2.5 million registered cases to make up the total of 10.8 million. There must, however, be doubts about the value of figures arrived in such a haphazard way. Where accurate figures of leprosy patients are available, as in Rumania, Cyprus and Libya, it has been shown that the WHO has exaggerated the true figure by from 10 to 50 times. In commenting on the WHO errors in the Cyprus figures, the Cyprus Director-General of Health emphasised that all the patients were old ones and no new cases had occurred in 1970, thus confirming the danger of drawing conclusions about the spread of the disease from prevalence figures. Countries which do have information about incidence rates, such as Okinawa, Hong Kong, New Guinea, Japan and Solomon Islands, Rumania and Cyprus, have all shown a decline. Although their figures will not be completely accurate, they are preferable to the WHO method of assessing the problem.

Most of the countries mentioned have a small leprosy problem. The most accurate information about incidence rates in highly endemic areas has come about in the following way. As no leprosy vaccine is available, BCG vaccine against the similar tubercle bacillus has been used to determine whether it has a protective effect againt leprosy. Trials have taken place in Uganda, Burma and New Guinea under the auspices of various research councils, and two trials have also been carried out in India using sulphones for their protective or chemoprophylactic effect by giving them to healthy people. All the trials were controlled by including a group similar in age range which was not protected with BCG or sulphones. At the start of trials the population was sur-

veyed, the leprosy cases were excluded and then new cases were recorded at repeated intervals of between one and two years. Thus, an annual incidence rate can be deduced and the control group will reveal the trend of the disease in these areas, which were deliberately chosen because of the serious leprosy problem.

The results of the BCG trial in Uganda and the two chemoprophylactic trials in India are shown in Tables 1 and 2. All the control groups shows a striking decline in the incidence of leprosy. These two trials took place in communities where sulphones are available to treat patients and, in contrast, the incidence of leprosy in New Guinea did not decline, staying constant at 6 per 1,000 per year from 1964 to 1969; sulphones were not available in this area until late in 1967. Therefore, the most likely explanation of the declining incidence rates is that sulphones given to leprosy patients kill *M. leprae* in a short enough time to interrupt transmission of the disease, thus confirming the experimental findings. The figures for new lepromatous cases are even more dramatic. In two of the areas not a single case was recorded in the controls and in the third the number fell from 11 to 2. Thus, the reservoir of infection has been virtually removed and this makes prospects of eradication bright. The chemotherapeutic and BCG trials were started over ten years ago yet delay in publishing the results fully and in coming to a conclusion about their efficacy has meant that a really effective method of prevention and eradication with sulphones is not being put into practice. If there is still any doubt about the conclusions to be drawn from these trials, these areas

could be resurveyed and the incidence rates recorded in the same age groups as those of ten years ago. There is other evidence based on outpatient incidence rates from two areas of India, Zambia and Uganda and from prevalence rates over a long period in Northern Nigeria, and former French Equatorial Africa (Gabon, Chad, Central African Republic and Congo-Brazzaville). All these have been summarised with my conclusions of the BCG and chemoprophylactic trials previously (*Lancet*, ii 1375, 1971; i, 1186, 1972; *Trop. Doct.*, **3**, 137, 1973). Also there is recent evidence of a decline in incidence in Burma and Thailand. Yet Ambrose, Davey and Browne have not mentioned these nor produced any quantitative information to support their own case.

If chemotherapy with sulphones does prevent the spread of the disease then treatment and prevention can be achieved by the same measure, the administration of the drugs to leprosy patients, especially those who are bacteriologically positive. Also by offering to the patients an incentive to attend for treatment, the affected group in the community is automatically brought under supervision, an immense practical advantage over other methods of prevention such as BCG and chemoprophylaxis, which depend on finding healthy contacts of patients. The main sulphone is dapsone which is extremely cheap, costing only 10p a year for each patient, and is easily administered by mouth once a week. Drug resistance is very rare, of the order of 3 per 5,000 lepromatous patients, and it has a wide margin of safety for toxic effects. Thus, mass treatment is practical and economically feasible if given in villages by

Table 1 Annual incidence of leprosy per 1,000 in control and BCG groups in the BCG leprosy trial in Uganda

	Control			Protected with BCG		
	Population examined	No. with leprosy	Annual incidence	Population examined	No. with leprosy	Annual incidence
1964	8,071	89	5.5	8,091	18	1.1
1966	9,036	54	3.0	9,052	1	0.05
1968	9,036	31	1.7	9,052	8	0.45

The incidence rate has been halved to give the annual incidence as there is an interval of two years between each survey.

Table 2 Annual incidence of leprosy per 1,000 in Andra Pradesh, India, in controls and chemoprophylactic groups: *A*, under 25 years of age; *B*, over 25 years of age

	A					
	Controls			Protected with Sulphones (Dapsone)		
	Population examined	No. with leprosy	Annual incidence	Population examined	No. with leprosy	Annual incidence
1965	11,270	54	4.79	11,452	29	2.53
1966	12,124	65	5.36	11,900	14	1.17
1967	12,116	37	3.01	12,157	9	0.74
1968	12,931	36	2.78	12,754	3	0.24
	B					
	Controls			Protected with Sulphones (Dapsone)		
	Population examined	No. with leprosy	Annual incidence	Population examined	No. with leprosy	Annual incidence
1965	8,104	90	11.10	7,851	91	11.59
1966	7,758	67	8.63	7,758	62	7.95
1967	7,337	38	5.17	7,511	45	5.9
1968	7,311	29	3.9	7,282	34	4.6

auxiliary staff who have been trained in diagnosis and treatment.

One area where this approach has been developed most widely is in northern Nigeria and was initiated by Ross. He carried out surveys, trained auxiliary staff and set up outpatient clinics in villages. Patients accepted this approach enthusiastically, whereas before there had been a poor response to treatment based on the leprosarium. In one area, 639 new patients appeared for treatment within 3 months of opening the clinics. There was little fear of stigma against the disease and Ross comments: "There is a degree of shame attached to infection by the disease. Nevertheless, leprosy is tolerated in village and social life and any fear of detection has been associated with the dread of being segregated which means separation from one's family". By 1968 there were 2,000 outpatient clinics throughout the northern region and most patients had access to treatment at an early stage. Unfortunately, few countries adopted such an approach so comprehensively; in many the leprosarium remains the only place where treatment can be obtained, patients have to travel long distances and they fear segregation. The numbers on treatment have remained low for these reasons and not because of lack of money as LEPRA claims in its advertisements. The cost of maintaining patients in institutions is enormously high and measures such as reconstructive surgery have added to the financial burden, making even less money available for work in outpatient clinics. Also, diagnosis is late; patients come late in the course of the disease and thus many are crippled and hence do not benefit from dapsone treatment.

Voluntary agencies in Europe collect more than £2 million annually for leprosy work, but most is still spent on institutional care—in May 1973, for example, the *Sunday Times* published an illustrated article showing the plight of severely crippled leprosy patients in India. At the same time LEPRA appealed for money. £20,000 was collected and in a letter to the *Sunday Times* on December 13, 1973, the Director of LEPRA gave details of how this money was to be spent. All of it was to be used on institutional care, accommodation and food, and on enabling patients to learn a trade such as footwear and cloth making; little money will go to curing and preventing the disease. As most of the patients are already crippled they cannot benefit from dapsone treatment. While there is sympathy for these patients' needs, surely the bulk of the money should go to prevention and cure with sulphones, which LEPRA claims is its aim. □

Accounting for energy

Dr Malcolm Slesser, Director of the Energy Studies Unit, Strathclyde University, sets out the basic principles of energy analysis.

IF economics is the science of scarcity and substitution, energy analysis is no more than the application of economic theory to the one commodity in ultimate limitation on Earth—thermodynamic potential. Perhaps the greatest conceptual difference between economics, as we know it today, and energy analysis lies in the 'system boundary'. Economics sets up a boundary around the system of interest; in energy analysis the system boundary is the whole planet.

Within the framework of economic thought, the economic process will automatically stimulate the development of another energy resource as one resource is depleted and its marginal costs rise. In effect, economics treats the world as a closed system having access to limitless amounts of energy, whose acquisition takes only time, capital labour and technology. On the face of it, it is a good deal easier to justify the position of the economists than that of the energy analysists, but it can be looked at another way.

Any production process, such as building a road or manufacturing pig-iron can only succeed if we inject capital, labour, materials and energy. Considering the properties of these inputs, capital is no more than labour, materials, capital and energy invested at an earlier time. If one goes on to examine every one of the inputs to any process one finds that these inputs are themselves the outcome of a process involving capital, labour, materials and energy. Indeed, the process of network analysis can go back and back until we find that the materials are ores in the ground or produce on the land and the energy is hydrocarbon locked in the

Earth or in deuterium atoms in a highly dilute state in the oceans; labour is mankind and capital has disappeared.

Although both energy and materials are mined and utilised, they have very different features. Materials are never destroyed; the iron molecule in iron ore is still an iron molecule when it is turned into steel and when it ultimately ends up as rust. Moreover, there can never really be a shortage of ores, since the oceans contain very large quantities. We are, however, long past that stage of global development at which ores can be obtained at sufficient rates simply by men labouring with picks and shovels. The energy required to win increasingly depleted ores and turn them into concentrated form will rise to enormous values. It is not the scarcity of the ores that is the problem.

When this thinking is applied to the two examples of making pig-iron and road building, it is certainly conceivable that, given enough poor and willing citizens, a motorway could be constructed by human labour alone. But no amount of human sweat can turn iron ore into iron, or iron into sophisticated machine tools. Though there is a well understood marginal energy cost for labour, so that the two can substitute one for the other to some extent, in the last analysis, energy does what labour cannot do. It carries out processes of transformation involving a decrease in entropy. Energy is irretrievably degraded once it has been used. All energy finishes up as waste heat, and must eventually be dissipated to the surrounding space. Labour, by contrast, is renewable and can also be upgraded through such processes as education and training. Also, as development has proceeded, labour, except in its most skilled forms, has become a surplus commodity in the greater part of the world.

Accordingly, energy analysts believe that it makes sense to measure the cost of the things done, not in money, which is after all nothing more than a highly sophisticated value judgement, but in terms of thermodynamic potential. On the other hand it is widely recognised amongst energy analysts that, as R. S. Berry has stated so succinctly, "if economists in the market place were to determine their shortages by looking further and further into the future, these estimates would come closer and closer to the estimates made by their colleagues, the thermodynamicists".

As energy analysis is concerned with the amount of global energy stock which must be sequestered to make a good or service, it is not enough to assess the amount of oil consumed to heat a house. What is of interest is the total amount of oil in the ground, to-

gether with any other energy sources, that had to be used to make that house heating possible. Thus we also need to know the quantities of energy that were required to win the oil from the ground, bring it from the oil field, refine it and deliver it to the consumer. In the UK these processes add about 18% to the apparent energy requirement for fuel oil for home heating. The error in ignoring the energy requirements for supply are in this case small, because the direct energy costs are the major component. But if we apply the same error to UK agriculture, for example, the direct energy requirements are a mere 42% of the total amount of energy that must in the end have been sequestered in order to make UK agriculture possible. This will have included the energy to make the tractor (duly amortised), pesticides, fertilisers and so on, as well as an appropriate share of the energy to make the machines that make the fertilisers, tractors and so on.

Until August 1974, various practitioners of energy analysis were, of necessity, formulating their own rules. In that month the International Federation of Institutes of Advanced Study IFIAS) held a workshop in Sweden, attended by twenty people from nine countries, at which the methodology and conventions of energy analysis were thrashed out. Its report is now available (*Workshop Report No. 6,* IFIAS, Stockholm; £4), and the following remarks follow its recommendations.

Perhaps the most fundamental observation is that since our concern with energy is its ability to do work, the calorific or heating values of fuels are not really the quality of interest. Rather it is a more subtle thermodynamic quality known to engineers as available work' which in turn closely equals a more easily derivable thermodynamic property, the Gibbs free energy. And indeed in any refined study in energy analysis such as the assessment of waste, for instance, it is the free energy that should be measured.

Nevertheless, the members of the workshop recognised that the calculation of Free Energy would not always be possible and is in any event little understood. For most situations an error of no more than 10% is incurred in taking enthalpy, that is the heating value of a fuel when it combusts with This quantity is called the Gross Energy Requirement (GER), normally expressed in megajoules (MJ) or gigajoules (GJ) per unit of output. The workshop defined it as "the amount of energy source or sources which are sequestered by the process of making a good or service". To obtain the 'energy' content, the workshop recommended the convention that it be taken as the

gross heat of combustion with air at 1 bar pressure and O °C.

The ramifications of this concept may be gathered from Fig. 1, in which is depicted a hypothetical production process in which natural gas, feed-stock hydrogen and silicon dioxide (from sand) combine to yield a product Y. Suppose that the energy to drive the process comes from coal. There are three system boundaries, of which the inner may be likened to the factory fence, and is essentially the system boundary a d o p t e d by company accountants.

The inputs entering through the inner boundary have to be prepared and delivered. Thus silicon dioxide must be refined by (say) acid treatment of sand, hydrogen must be made from natural gas, and natural gas must be brought to the factory fence. These additional processes are depicted by the middle system boundary, somewhat analogous to the nation state. But in the end all the inputs derive from a source in or on the ground—the outer system boundary. In estimating the GER it is essential to go back to this level. Of course, if one's interest is in the energy efficiency of a given sector of a process, then one may choose to examine what happens in the transfer through one boundary to another. This is referred to as the Process Energy Requirement.

Another valuable permutation is that of Net Energy Requirement (NER).

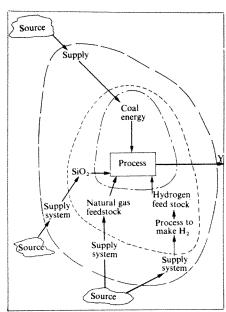
Fig 1: hypothetical production process


Table 1 The ERE for UK fuel industries

	1963	1968	1971-72
Coal	0.047	0.042	0.047
Gas	0.48	0.390	0.23
Oil	0.23	0.134	0.11
Electricity	3.54	3.192	2.98

Source: Chapman et al., Energy Policy, Sept. 1974.

This is useful in cases in which the product is itself a combustible item, such as a plastic product or a refined fuel. It takes into account the fact that the product has a future potential as a fuel. Clearly in the argument as to whether a plastic or a glass bottle is the less energy intensive, it aids the proponent of plastic bottles to take the NER, rather than the GER, while the manufacturer of the glass bottle cannot take anything but the GER.

Of all the uses of energy analysis and the use of Gross Energy Requirement, perhaps none is more spectacular than the concept of the Energy Requirement for Energy (ERE) defined as (energy of the resource sequestered—energy delivered to point of use)/energy delivered to point of use. Here we use energy analysis to assess the amount of energy that must be sequestered in order to make energy available. Table 1, for example, relates to some recent UK figures. It shows some facets of our energy industries that are not normally apparent. Thus the efficiency of fuel use for electricity generation is rapidly rising and now exceeds an average thermal efficiency of 31% at the power station. But if one allows for the energy required to get the coal and nuclear fuels to the power station, the energy dissipated in the grid and that used by the electricity boards themselves, the final ERE for electricity in the UK today is barely below 3.0. That is to say, for every unit of electricity consumed by the public (1 kWh = 3.6 MJ), some 14 MJ of energy have been sequestered.

Estimating energy requirements is not unlike cost accounting with an element of quantity surveying thrown in. One should recognise that various levels of accuracy are necessary. The direct inputs to a process under study must be estimated accurately. But the inputs to the inputs may generally be treated with a lower order of accuracy. Thus if the problem is to estimate the GER of a field of barley. one needs to know the actual inputs to the barley field. These will comprise such things as tractor fuel, nitrogen fertiliser, phosphorus, pesticide and so on. But the GER to make nitrogen fertiliser need not generally be estimated in such detail. Indeed an industry-wide aggregate based on the GER per unit of nitrogen would be sufficiently accurate. In the same way the machines to make the factories to make the inputs represent a very small part of the whole process, and may be obtained at adequate accuracy from such devices as economic input-output tables.

Perhaps the greatest room for dispute and error is in the partitioning of the GER between two or more products of one process. In economics, market forces dictate partitioning. In energy

analysis, the market mechanism has yet to develop. For example, how does one partition the energy requirements in the case of the electrolysis of common salt to yield chlorine and sodium hydroxide, for each of which the current price is different? The IFIAS workshop recommended that this be done on the basis of some physical parameter, not on notions of value.

Energy analysis has been cursorily dismissed in some economic circles as being no more than "a BTU-theory of value". Energy analysts, however, would neither claim as much nor as little. The potential for energy analysis still has to be tested, just indeed as economic analysis has still to show whether it is sufficiently developed to deal with such problems as resource scarcity or a step change in the price of energy. I shall merely indicate here a few of the areas where energy analysis is being tried out and suggest that it is a logical area of endeavour.

What will be the price of ammonia fertiliser in 1990? It would be a brave man indeed who was prepared to extrapolate price trends that far ahead. Even to guess at a figure for six months from now would have its uncertainties. By using energy terms, the uncertainty largely vanishes. Figure 2 depicts how the GER for ammonia has changed with time since its first synthesis in in 1912. Note how the GER appears to be flattening out at some 2.5 times the theoretical (thermodynamic) minimum. Now the thermodynamic minimum energy presupposes an infiinitely slow rate of transformation—clearly not a practical state of affairs for a world that is looking for large amounts of ammonia every day. It is now clear that there is a trade-off between energy and haste of production, and a study of the new, really large (300,000 tonnes a year) ammonia plants suggest that the technological minimum at that rate of production will be not far from the value of 2.5 times the thermodynamic minimum. This simply arises from the need to have preheaters, coolers, heat exchangers and furnaces that are less than 100% efficient.

We can therefore forecast with reasonable accuracy that the GER for ammonia in 1990 will be about 45 MJ kg^{-1}.

Where less developed processes are being dealt with, of course, an assessment must be made of the effect on the GER of technological improvements and growth in the scale of operations. Economic theory would have to be used to find a means of assessing how quickly these changes might come about under the pressures of demand and supply.

Since all energy is conserved, but high quality energy is degraded to waste heat, waste has several connotations.

In one sense it is the use of more energy than necessary to effect a given transformation. Energy analysis provides the tools for looking at this problem, though it does not of itself provide the answer. Gyftopolous and associates (in *Potential fuel effectiveness in industry*, Ballinger, Cambridge, Massachusetts, 1974) estimated the Gross Free Energy Requirement (GFER) in various production processes in the USA and found that iron making, at 4.16 times the thermodynamic minimum, was much more efficient than the aluminium industry (7.6), petrol (10) or paper making (170).

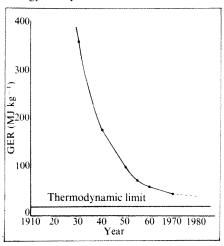
But there is another sense in which energy analysis can examine waste. It


Fig 2: GER for ammonia manufacture

is now recognised that energy dissipation in highly industrialised areas can create climate modification and some climatologists are suggesting that, globally speaking, an energy dissipation equal to 1% of the incoming solar energy or even less may be an upper limit for the planet. As we approach this limit, probably in the middle of the next century, the matter of interest is not the energy dissipated by the factory in Sheffield, but the energy that had to be dissipated in order to make the Sheffield factory function. And that has to be aggregated over the whole globe. This is exactly what a GER calculation allows one to do so easily.

There are many views of the future energy situation and how the price of oil will vary. It is reasonable to argue that in intelligent hands (and OPEC is intelligent) the price of oil will be slightly lower than its substitution price. But economic substitution calculations based on pre-November 1973 energy prices are now incorrect, because the stepchange in the price of oil has raised the cost of the inputs necessary to furnish alternative forms of energy. So calculation of that substitution price is a very tricky matter. Why not re-express the problem in terms of ERE?

In 1972 it was reckoned that Colo-

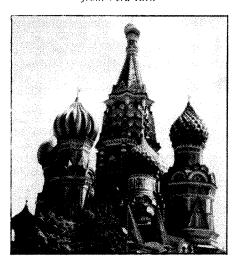
rado shales would be exploitable at an energy price of $6 a barrel, that is when oil prices reached a price of $6 per barrel (US Energy Outlook, National Petroleum Council, USA). At that time energy cost somewhat less than $1 a gigajoule. Allowing for others costs and profit, we deduce that the GER for shale was and is around 5 GJ per barrel. The energy in a barrel of shale oil is about 6.5 GJ per barrel. Thus shale production gives a net ERA of about 0.3. King Feisal is still sitting pretty.

Such figures are clearly very tentative and not backed by good data. But the data are obtainable.

The ceiling to energy prices will be set when the ERE for unlimited energy is known. Our likely sources are fusion and solar. At the moment the ERE for solar energy by photovoltaic methods is around 2—hopelessly high. New technology in the pipeline may reduce that by a factor of six to 0.33—better than Colorado shale — but another order of magnitude is needed before solar energy sources can compete with Middle East oil at the well head. The ERE for fusion is a matter for conjecture. In laboratory studies it is still hopelessly high.

And so, finally, we come to the logical intermediate step—to assess the GER to save energy rather to produce it. What, for example, is the GER to double glaze and insulate a house, and what is the GER saved thereby each year? When energy was cheap, economic calculations came up with different solutions. Now they are tending to come to the same solutions and people, using their own horse sense, are insulating and double glazing their homes and are finding it an extremely attractive long term gain.

One of the most telling uses of energy analysis has been the pioneer work by Chapman and Mortimer at the Open University and by Price at Friends of the Earth in their dynamic analysis of nuclear reactor building programmes. They show that no crash programme of nuclear reactor construction can ever meet an energy gap, because of the huge energy investment needed; indeed a net energy deficit would be created for the first eight to eleven years of the programme. At Strathclyde we have carried this analysis a step further using system simulation techniques to examine a range of energy scenarios for the UK to the year 2 000. Though a great deal hinges on the quality of uranium ores that will be available, there seems to be no way a steam generating heavy water reactor system can sustain the rates of economic growth hoped for. Here then, is a new methodology, an old language and a familiar problem—the problem of allocation of resources. □

international news


As the current five-year plan draws to its close, considerable concern is evident in the pronouncements of the Central Committee of the Communist Party of the Soviet Union (CPSU) about the lack of progress in the Soviet research and development programme. According to *Pravda* (February 11, 1975), the plans for implementing new technological advances have not been fulfilled in "a number of enterprises of the Ministry of Power Production, the Ministry of Ferrous Metals and the Ministry of the Coal Industry. In several teams at Institutes of Higher Education, regular work on pressing problems of science and the national economy has been replaced by vain bustle between petty and inefficient themes. The possibilities of mutual exchange of achievements between enterprises, institutes and branches are not being used to the full. ... In certain institutes up to 40% of the work completed has not been realised for years". The Central Committee stresses the need for the appropriate ideological means to be taken to "put into action all reserves for accelerating scientific and technological progress", in particular, the improvement of the organisation of "socialist emulation" among the scientists and technologists concerned.

● The announcement of a new *samizdat* journal, *Twentieth Century,* edited by Roy Medvedev (the twin brother of geneticist Zhores Medvedev, who was deprived of his passport in 1973) raises once again the question of academic dissidence in the Soviet Union. Although Roy Medvedev, together with physicist Valentin Turchin, was a co-signatory of Sakharov's second "Manifesto" (1970), over the past few years there has been an increasing gap between the brands of dissidence expressed by Roy Medvedev and Sakharov. The new journal is a successor to the *samizdat Political Diary* of the late 1960s, which took, in the main, a Marxist viewpoint, although critical of the Kremlin's interpretation of Marxist–Leninist principles. It would seem that Roy Medvedev and his contributors envisage *Twentieth Century* as an alternative press for the loyal opposition—a halfway house between the official establishment journals and the more outspoken dissidence of the *Chronicle of Current Events.* The latter reports cases of breaches of constitutional

rights and the fate of prisoners of conscience, as well as discussing general issues. On the other hand, *Twentieth Century,* to judge from the contents of the first issue, seems likely to concern itself primarily, if not entirely, with theoretical debate.

Meanwhile, at the other end of the spectrum of dissidence, the appeal of Dr Mikhail Shtern against his eight-year sentence still remains postponed and unheard. His son, Avgust, who re-

Russia today

from Vera Rich

cently arrived in Israel, connects the sudden granting of his visa with his father's predicament. It is, he says, more "convenient" for the prosecuting authorities that his father should be alone, without the support of his family; it seems, in fact, that his own visa was granted on an 'either/or' basis, which left Avgust little choice but to depart for Israel. He stressed that his father is now in a very precarious state of health and that, under prison conditions, the after-effects of an old injury from a car accident could at any time produce paralysis. In his concern for his father, Avgust seemed unwilling to discuss the details of the accusation, except to state that his father has not broken or contravened any Soviet laws. He stressed, however, that Dr Shtern's chances of surviving an eight-year sentence are minimal and that only a successful outcome of the appeal can save him.

One dissident who has survived his term of imprisonment is Ilya Glezer, a neurobiologist, who was sentenced in

1972 to three years in a labour camp and three years "exile" (in Siberia). A massive appeal (151 signatures) was organised on Glezer's behalf by scientists and physicians working in related fields, asking that in the interests of international good-will he should be exiled not to Siberia but to Israel. Nothing, however, has been heard of Glezer's whereabouts since the expiration of his term of imprisonment on February 7, and it would seem therefore that the appeal has been ignored or denied.

● The Lomonosov medals for 1974 were awarded to Academician Aleksandr I. Tselikov for his work in metallurgy and metal technology, and to Angel Balevskii, President of the Bulgarian Academy of Sciences, also for his work in metallurgy. The Lomonosov medals are the highest awards of the Academy of Sciences of the USSR; two are awarded annually, one to a Soviet and one to a foreign scientist.

● The *Novosti* agency reports that a team of Leningrad scientists has developed a computer-controlled robot with laser "eyes" and a crab-like walking motion. According to the team spokesman, Mikhail Ignat'ev, it has high cross-country ability with minimum energy consumption, and is several times cheaper than a comparable air-cushion craft. It can automatically set itself to proceed at any speed from a walking pace to a "gallop", and can lift loads of up to half a ton. Ignat'ev suggests that it could be of great use in enabling geologists to cross difficult terrain—dense forests and steep mountain slopes. The team is now at work on a model which will not run down any saplings growing in its path, thereby conforming to conservation requirements.

● The February 1975 issue of the popular science journal *Priroda* carries a headline in its news section that at first glance seems an ominous echo of Lysenkoism—"Hybrid of a herb and a tree". In fact, however, the hybridisation reported is simply that of two species of *Nicotiana*—the dendroid smoking tobacco *N. glauca* and the flowering *N. alata* used in horticulture.

The research, which was carried out at the Principal Botanical Garden of the Soviet Academy of Sciences rseulted first of all in sterile hybrids which were then, it is claimed, converted by "colchicinisation, leading to doubling of the number of chromo-

174

somes and normalisation of the formation of sex cells" into fertile amphidiploids. It is hoped that the hybrid will form "interesting material" for the selection of disease-resistant strains of smoking tobacco—a revealing sidelight on Soviet public health planning, which, although greatly concerned with the fight against alcoholism, shows no signs of following this up with an anti-smoking campaign.

● Examination of the photographs of the Sun from the Salyut-4 mission have revealed considerable differences in the clarity of pictures taken by the same telescope, even on the same day. Although for the mission due allowance was made for the possibility of the condensation of fine particles on the optical elements, and the reflecting surface was deposited on the mirror immediately before observations were to begin, it would seem that this was not enough. In one case, one of two photographs taken only a short time apart shows a distinct image with good contrast, whereas in the other the Sun is "hardly" visible.

The Soviet space programme has always been considerably automata-oriented—the early cosmonauts being little more than human test animals in their craft. A brief note in *Pravda* on the quality of the photographs is, therefore, perhaps, of more than passing interest. After reporting that the scientists of the Crimean Astrophysical Observatory of the Soviet Academy of Sciences are now engaged in evaluating the photographs and in relating them to the spectrograms obtained with special reference to protuberances and flocculae, it wryly remarks that the scientists hope that the cosmonauts who actualy operated the orbital telescope may be of "great help" in this task.   □

Energy costing in the fields

by Eleanor Lawrence

THE Agricultural Research Council has recently made public the results of a Working Party on energy in agriculture which was commissioned by the relatively new Joint Consultative Organisation for Research and Development in Agriculture and Food. The report was intended to provide an appraisal of the use of energy in British agriculture and recommend ways in which agriculture could use this energy more efficiently while continuing to increase its productivity.

According to the overall energy budget calculated in the report, British agriculture at present uses only 3% of the annual national energy requirement to produce just over 50% (on the basis of cash value) of the nation's

food. Impressive as this figure is, it is difficult to find out from the report whether in fact this 3% is being used as efficiently as it might be, as ultimately the energy which makes agriculture possible comes of course from an unlimited outside source, the Sun, not taken into account in energy analysis calculations, and there are no figures given for the ways in which different levels of the inputs (fertiliser, agrochemicals a n d mechanisation) affect production.

Figures are given however for the proportions of the agriculture energy budget spent on petroleum, solid fuels, fertiliser and so on which can perhaps give a rough guide to where economies might begin. Petroleum accounts for 34% of the total budget, followed by fertilisers (29%) with machinery and electricity also taking a substantial share.

When figures are given for the ratios of energy (excluding solar energy) input to energy output as metabolisable food energy for various crops and animals they are on the face of it rather alarming even for some of the plants which have the supplementary input of solar energy. But the real question in trying to determine where economies are to be made is to what degree the necessary high levels of production are absolutely dependent on these massive energy inputs. Although the report does discuss this in general terms some facts and figures would have been very useful at this point.

The recommendations in fact concentrate on simple 'waste not' policies; a better use of nitrogen fertiliser, recycling of farm wastes, and some recommendations for research involving a better use of the unlimited energy sources, such as improving the photosynthetic capacity of plants and finding ways of applying biological nitrogen fixation to a wider range of crops. The recommendations often seem not to arise from the energy analysis itself but from the 'old-fashioned' experimental data discussed in the text.   □

Heavenly teacher for Indian pupils

from Narender K. Sehgal, Jullundur

IF all goes well and there are no further postponements, India will in July this year embark on an ambitious experiment in mass education. At the heart of it will be a $205 million American satellite launched in May last year from the Kennedy Space Center in Cape Canaveral, Florida. The most expensive unmanned satellite ever launched by the USA, the Applications Technology Satellite 6 (ATS 6) is designed, among other things, to help

increase literacy in India, and bring televised medical care to Alaska and special educational programmes to rural America.

According to a 1969 Indo-American agreement, the USA will let India use the 1,500 kilogram spacecraft for a year to beam educational television programmes in regional languages to selected villages in the Indian countryside. Called SITE (Satellite Instructional Television Experiment), the project is being coordinated by the All India Radio (AIR) and the Indian Space Research Organisation (ISRO), with assistance from UNESCO, the United Nations Development Programme (UNDP) and the International Telecommunication Union (ITU). Originally planned to start in 1973, SITE got delayed because of two postponements in the satellite launch. The project will now get under way in July 1975 when ATS 6 will be shifted to a position 36,000 kilometres above Kenya. From there, the satellite will receive specially prepared programmes from the Delhi and Ahmedabad stations and relay them to several thousand ground receivers in India. Out of the 6,000 villages in six states—Andhra Pradesh, Bihar, Karnataka, Madhya Pradesh, Orissa and Rajasthan—chosen for the purpose, some 2,400 will employ specially designed 'direct-reception' television sets which will pick up programmes straight from the satellite. Others, within the range of ground transmitters, will use conventional television sets.

An ISRO-built direct-reception television system was recently tested at the NASA Goddard Space Flight Center. During tests, it successfully received signals from the ATS 6. The system transmitted television test patterns from the earth station in Rosman, North Carolina, to the ATS 6.

According to officials of the AIR, by the time the satellite is moved into its appointed position, 35% of the educational programmes intended for use in SITE will have been recorded on video tape. The Earth station at Ahmedabad—modified with assistance from the ITU to transmit as well as receive television signals—will transmit to the ATS 6 these recorded programmes, which will cover education, agriculture, health and family planning. There will also be live transmissions, originating from a television studio at Ahmedabad—built with assistance from the UNESCO—which will include a 10-minute news broadcast each day. The ITU and the UNDP are also providing assistance for the installation of a low power television transmitter, as part of SITE, at Pij, a village near Nadiad in Gujarat. A total of about 1,500 hours of educational programmes will be

SWEDISH students are losing interest in research, especially in mathematics and the natural sciences. The change is part of a general movement away from full-time, examination-oriented university students straight out of school to older, part-time students who have already been employed for a number of years and who take short courses immediately relevant to their jobs and interest. The percentage of part-time students enrolling for the autumn term in Swedish tertiary educational institutions has grown continuously from 12% in 1969 to 29% in 1974.

Students used to compete for a place in a Swedish university. With increasing graduate unemployment, however, the situation began to change, and university applications have been declining since the 1968–69 academic year. This has stimulated the universities themselves to find a new type of student. Members of the new group are, on average, between 27 and 30 years old, have worked for a few years and want to study to enrich interest in the job, without necessarily taking an examination at the end of the course. A typical example is of company employees taking a short course in the economics of the firm. Of all the students who enrolled for this course in the spring term of 1974, only 15% intended to take the examinations.

The trend towards shorter courses has been institutionalised in 'distance teaching': a scheme rather like the UK's Open University except that, instead of centralising the courses under one authority, each of the six Swedish universities runs its own programme. Experiments with these courses have been running on a small scale for a couple of years. But with facilities established for the part-time student without daily access to an educational institution, the trend towards more short courses will probably continue.

All this is obviously beneficial for the new part-time students, but the general trend raises serious questions about the future of academic research. Although short courses in ecology and environmental protection are popular, biology as such has very few takers. There is no lack of applicants for short courses in electronics, energy forms and protection against radiation, but the number of students in mathematics and

Letter from Sweden

from Wendy Barnaby, Stockholm

the natural science faculties has fallen off. Although the surplus of university graduates has been forecast to persist throughout the 1970s, it is predicted that demand from the labour market will catch up with and outgrow supply early in the 1980s. This could have serious consequences not only in the general labour market but also within the universities themselves, in maintaining the number and quality of teaching staff. And it looks as though the country's capacity for scientific research may suffer.

● How would you get rid of your old car if you lived in the countryside far from a scrapping firm, and transportation costs were high? Many Swedes faced with this problem leave cars to rot in country dumps or simply abandon them on by-roads. A recent report commissioned by the Swedish Department of Agriculture suggests measures which could be taken to stop such understandable neglect. According to the report, recirculation of metal and other wastes could save an increasing proportion of the total energy used in Sweden.

The report foresees that recycling could save energy equivalent to 31,000 cubic metres of oil annually, or somewhat less than 1% of the country's total energy requirements. That such a small proportion is seen as justifying a reorganisation of the waste system is indicative of the current energy-consciousness in Sweden. In this affluent, packaged country, where the average household produces 270 kilograms of waste a year a person, scrutiny of energy saving measures is no longer confined to nuclear reactors, wind trappers and sun catchers—it also includes the humble kitchen bin.

The report estimates that more than 20% of household waste could be recycled. At present 70% of the average Swedish kitchen bin is filled with paper, and together these bins produce 780,000 tons of paper a year. The report recommends that householders should be made to separate out the paper from their other garbage, making it easier and cheaper for the municipalities to collect and recycle it. Chemical wastes should be recycled, dumped or deposited on a long term basis by a company jointly owned and run by the government, municipal authorities and industry. And to discourage the dumping of cars, the report proposes a co-operative system of authorisation for scrapping yards and a levy on new cars. The levy, suggested to be Skr.400 (about $US90), would be placed on every new car sold in Sweden after July 1, 1975. When the last owner of the car wanted to dispose of it, he would take it to an authorised scrapping firm (one that met conditions for car disposal, re-sale of spare parts and so on) which would issue a receipt. On presentation of this receipt to the local authorities the owner would be refunded the levy plus a bonus of Skr.100. Since the average life of a Swedish car is 9 years, the system would pay for its own administration as well as providing subsidies to municipal authorities for cleaning up old junk-yards and abandoned cars.

broadcast during the one year experiment. Following the 1969 Indo-US agreement, the SITE Group, specially created in 1970 at Ahmedabad, was charged with the full responsibility for planning, management, operation and evaluation of the experiment. If SITE proves successful, ISRO has its sights set on a multipurpose satellite for providing nationwide television coverage and telecommunication links between Delhi, Bombay, Madras and Calcutta.

In practice, one of the most challenging tasks that SITE is likely to come up against, when the experiment actually begins, will be to keep all the 6,000-odd television receivers (the conventional ones as well as the more expensive direct-reception type) in good working order. This is going to be far more formidable a job than it might appear at first sight. The Haryana government a few years ago installed community television sets in villages within reach of the television station in bordering Delhi. But a check after a short while revealed that most of the receivers had gone wrong because the authorities had not taken steps to ensure proper care, handling, upkeep and maintenance of the sets that were installed. The SITE managers will, one hopes, not allow this to happen.

The SITE project will in many ways be a unique venture. It will, for the first time, demonstrate that relatively inexpensive receivers (the ones built by the ISRO are said to cost about twice as much as the conventional sets) can be used to receive television programmes directly from a satellite. Moreover, such a system could open up immense possibilities and greatly enhance the chances of reducing illiteracy within a relatively short period of time. That is why, ISRO officials believe, SITE results will be of interest to many other countries. □

correspondence

Facts

SIR,—Although I am reluctant to advertise my own philosophical wares in your correspondence column, I believe that some distinctions and definitions made in my book *Scientific Knowledge and Its Social Problems* may be useful for removing some of the confusions referred to in your leader "No longer so much solid ground" (February 13).

There I constructed a sequence of stages of development of materials towards the condition of being "facts" or "knowledge"; and in this it was clear why the published "research report" is not, and cannot be, completely reliable fact. In brief, I start with the problem, and consider the essence of scientific work as the *investigation* of problems (involving creation as well as solution). Contact (necessarily partial and indirect) with the external world is made in the production of *data*, this is then refined to form *information* about the conceptual objects of the scientist's enquiry. But the problem is solved by the *conclusion* to an argument about these objects; and in this structure the information functions as *evidence*. Of course, there is a cyclic interaction between the different phases of this work; and since logical certainty is never possible, it must be governed by socially imposed criteria of *quality* and *value*. For this reason, the social mechanisms of *quality control* are essential for the progress of science; *shoddy* and *vacuous* work (easily explained in this schema) are as "natural" as good work. The *published research report* stating conclusion and evidence is therefore fallible in a number of respects.

The *social* phase of the achievement of scientific knowledge proceeds by judgements of disinterested, competent colleagues. They ask: is this report *relevant* to my enquiry, and if so is it *reliable* for use? If it passes both these tests, it enters the current stock of *tools* for future work. There, it is *transformed* in various ways, depending on the context (descendant problems, application elsewhere, or teaching). If there remains some content that is *invariant* under the inevitable changes in meaning of its terms, then we can call it a *fact*. Facts which survive the demise of the area or field in which they took rise, are then considered as very reliable facts, or bits or *scientific knowledge*.

To be brief, I have omitted all mention of the elaborations of this schema, and of its unsolved philosophical problems. But it seems to provide a reasonable schema of scientific work, and a vocabulary for describing its products.

Yours faithfully,
JEROME R. RAVETZ
London EC4

Probability

SIR,—I wish to suggest the use of a notation which I have found handy, and which seems to fulfil a real, if minor need. It is often necessary to use the phrase "the probability (of some foregoing value or result) under the null hypothesis" or, equivalently, "the probability, given H_0." I recommend that this phrase be rendered as $p \mid H_0$).

Yours faithfully,
M. HAMMERTON
University of Newcastle upon Tyne

Food and allotments

SIR,—Your correspondent F. P. Hughes of Ontario, Canada (February 27) is right in stressing the possible importance of allotments in alleviating a food shortage, but he overstates his case. Allotments in Britain certainly did not produce more than half our food during the world wars. During the 1939–45 war there were 1,500,000 allotments, covering rather less than 150,000 acres of land. There were perhaps as many plots, of a similar area, on which vegetables were grown in private gardens. This area of some 300,000 acres made a useful contribution, perhaps as much as 5%, to our food supplies. It would be difficult to exceed this proportion in most Western countries.

Yours faithfully,
KENNETH MELLANBY
Monks Wood Experimental Station, Abbots Ripton

Teleological vs teleonomic

SIR,—Larkins, MacAuley and MacIntyre (*Nature*, November 29) suggest "a teleological explanation for the siting of the 25 HCC-1-hydroxylase enzyme system in the kidney tubule, where it is able to sense and respond to fluctuations in calcium concentration in the main outflow site from the extracellular compartment".

I take issue with the use of the word teleological in that context. Teleology is defined as the "study of evidences of design in nature". and design as "a

deliberate purposive planning". I doubt that this is the kind of explanation intended by Larkins *et al.* for the siting of an enzyme system in the kidney.

C. S. Pittendrigh in *Behaviour and Evolution*, suggested that the word teleological should be reserved for cases where the idea of the end (goal) precedes the use of the means, and the word teleonomic for cases where the ends result from means that lack design (intent)—as when adaptive traits are produced by random mutations and natural selection.

Accordingly, I suggest that the explanation offered by Larkins *et al.* is teleonomic.

Yours faithfully,
WILLIAM H. GILBERT
*Colby College,
Waterville, Maine 04901*

Taboo research

SIR,—Your correspondent H. Fraenkel-Conrat (March 6) makes one wonder whether after all there are not "two cultures".

Scientists should not think of themselves as the present-day equivalents of Plato's philosopher–kings, who "do good" to the rest of society whether we all will or not.

Robert Boyle wrote that "Gentlemen and scholars are apt to look upon the inquiry into manufactures as a Mechanick employment; and therefore beneath them". We do have, however, HM Factory Inspectorate, with a sound basis of rational "scientific" judgment; and on that basis, we, the whole of society, decide what kind of, for example, dusts, we shall allow in our working lives, and under what conditions and how we shall regulate our exposure to the hazards of our technological culture. By the same reasoning we should surely, the whole of us, decide what it is reasonable to do about self-replicating macromolecules.

Furthermore, Fraenkel-Conrat writes as though there were nothing else to the future of man but his material well-being; surely this is a Procrustean contraction of our attitude to and place in the cosmos—it may well have been for this reason that Prometheus was condemned by the gods to such a cruel punishment as to have his vitals continually eaten by predatory birds and then renewed?

"Man shall not live by bread alone".

Yours faithfully,
R. A. DAVIS
Surbiton, Surrey

Island biogeography and the design of wildlife preserves

from Robert M. May

ISLANDS have always fascinated ecologists. From the early days of Darwin and Wallace, to the analytical theory of island biogeography developed by MacArthur and Wilson, islands have served as ready made 'evolutionary laboratories' for the development and testing of ideas about the structure of plant and animal communities.

One major aspect of this work seeks to relate the number of species present to the area of the island (which may be a real island in the ocean, or a virtual island such as an isolated hilltop or a wildlife refuge). One rough rule, which fits a surprisingly wide variety of data, is that a tenfold decrease in area corresponds to a halving of the equilibrium number of species present.

In detail, such species–area theories have two components. The first concerns the statics, and seeks to show that there is an equilibrium number of species, S, which is appropriate to an island of given area, A (and that $S \sim A^z$, with z typically in the range 0.2 to 0.3). The second part concerns the dynamics, the way the equilibrium is maintained by a balance between extinction and immigration. One line of evidence comes from studying the increase towards equilibrium on islands where the flora and fauna have been removed either by natural catastrophe (as in the case of Krakatoa in 1883), or by experimental manipulation (as in the removal of the arthropod fauna from tiny, four square metre, islets off Florida by Simberloff and Wilson). Similarly it is revealing to monitor the initial colonisation of a newly created volcanic island such as Surtsey. A second line of attack is to study the way the balance is maintained on islands which are thought to have settled into their equilibrium state (for example, some of Lack's studies, or Diamond's study of the California islands); such work is frequently beset by problems in estimating man's effects on natural turnover rates. A third approach focuses on offshore 'land bridge' islands, which in the heyday of the last ice age some 10,000 years ago

(when the oceans were typically 100 metres lower) were part of the mainland area; as these islands have been created by the rising oceans, their rich complement of mainland species has slowly declined towards the island equilibrium value. Studies by Diamond on land bridge islands in the vicinity of New Guinea, and by Terborgh (chapter 24 in *Tropical Ecological Systems*, Ecological Studies Vol. 11; Springer-Verlag, 1975) on neotropical land bridge islands such as Trinidad and Tobago, show a very consistent pattern in their rates of relaxation towards equilibrium in the species number.

Recently several people have observed that these notions have relevance to the design of national parks and wildlife preserves.

At a qualitative level, it follows that the number of species naturally maintained at equilibrium depends on the size of the park. Many species will not cross major highways (for good reasons!), and for these species the effective area of the park is halved by bisecting it with a big road: about one sixth of all such species will be gone when the system settles to its new equilibrium. In cases where one large area is infeasible, it must be realised that several smaller areas, adding up to the same total as the single large area, are not biogeographically equivalent to it: they will tend to support a smaller species total. One way to raise the equilibrium number of species in any one such smaller park is to raise the immigration rate into it. This can be done by judicious juxtaposition of the scattered parks, and by providing corridors or stepping stones of natural habitat between them. These and other aspects of the "geometry of wildlife refuges" have been developed by Jared Diamond in an invited address at the 16th International Ornithological Congress in Canberra, 1974 (proceedings to be published), and by E. O. Wilson and E. O. Willis (in a chapter of *Ecology of Species and Communities*, to be published by Harvard University Press, 1975).

These articles represent but the beg-

innings of the subject. They ignore, among other things, epidemiological aspects of park management: many scattered parks have over a single park the advantage that not all eggs are in the one basket. Moreover species–area relations only aim at a coarse-grained first approximation to the floral and faunal dynamics. They do not incorporate such things as the spatial and temporal patterns of stable oscillation which so frequently characterise populations both in mathematical models and in the real world. The botanical evidence for a 50 year cycle in elephant irruptions in the area that is today Tsavo National Park at the foot of Mount Kilimanjaro (for example, G. Caughley, *E. Afr. Wildl. J.*, in the press) suggests that such dynamic features of natural populations can create management problems when even a very large area is enclosed.

One example of a quantitative application of these ideas is given by M. B. Usher's study of the relation between the areas of twelve nature reserves in Yorkshire and the number of species of higher plants growing in them (in *Biological Management and Conservation*; Chapman and Hall, 1973). The observations fit the relation $S \sim A^{0.21}$, with the park areas varying over more than two orders of magnitude.

A particularly nice calculation has been made by John Terborgh, in the article referred to above. For the West Indian land bridge islands, he knows the number of bird species currently to be found on a given island, and can estimate (from the neighbouring mainland species abundance) the number which were present before the island was cut off 10,000 years ago. This gradual decline in species number on the islands may be described by an equation

$$dS/dt = kS^2 \qquad (1)$$

Here k is a measure of extinction rate, and Terborgh takes the overall loss rate to have an interactive form, proportional to S^2, to account for the fact that species hasten each other's extinction. A more detailed empirical and

theoretical justification for the use of this equation was independently given by T. W. Schoener at the 16th International Ornithological Congress, mentioned above. The extinction rate k may now be calculated for each island. As expected, the k values have a systematic dependence on island area.

Now comes the payoff. The island of Barro Colorado was created with the formation of Lake Gatun in conjunction with the construction of the Panama Canal, and since 1923 it has been carefully protected as a wildlife preserve. A meticulous account of the bird species present on the island over the past 50 years has recently been published by E. O. Willis (*Ecol. Monogr.*, **44**, 153–169; 1974). From the k-versus-area patterns of West Indian land bridge islands, an estimate of the k value for Barro Colorado island may be obtained. Equation (1) can then be used to get an independent estimate of the decline in the island's number of bird species since 1923. Terborgh's theoretical estimate of 16–17 species lost is reassuringly in accord with the actual number observed by Willis, namely 15.

Proteins which bind polyenes and react with photons

from A. J. Thomson

UNTIL a decade ago rhodopsins were the only proteins known to employ a retinyl polyene as a prosthetic chromophore. A large number of rhodopsins have been found (see Knowles, *Nature*, **253**, 394; 1975). All have the common feature of the 11-*cis* conformation of the polyene chain which in the examples investigated is bound to the protein through a protonated Schiff base linkage. The action of light is to produce the all-*trans* isomer with concomitant loss of a proton.

Three additional types of protein–polyene complexes have been discovered within the last few years, revealing an intriguing variety of functions and a satisfying economy of use of prosthetic group. The newcomers, in order of appearance, are first the yellow vitamin A transporting complex, called retinol binding protein (RBP), characterised by Kanai, Raz and Goodman (*J. clin. Invest.*, **47**, 2025; 1968). This protein stabilises and solubilises in water all the mono-*cis* and the *trans* isomers of vitamin A. No photochemical reactions of this complex have been reported. The second, retinochrome, was found by Hara and Hara (*Nature*, **206**, 1331; 1965) in various kinds of cephalopod retina, such as that of the Japanese squid. This protein absorbs maximally in the range 490 to 522 nm and contains the all-*trans* isomer of the retinyl polyene bound to the protein by a Schiff base link, probably protonated. The action of light is to release the 11-*cis* isomer of retinol. The most surprising of the newcomers, however, is bacteriorhodopsin, a purple pigment found in the outer membrane of the bacterium, *Halobacterium halobium*, when it is grown in low oxygen tension (Oesterhelt and Stoeckenius, *Nature new Biol.*, **233**, 149; 1971). Containing the 13-*cis* isomer of the retinyl polyene chain linked to the protein also by means of a protonated Schiff base, the action of light is to produce the all-*trans* isomer with the loss of a proton. The polyene chain is not detached from the protein but returns in a dark, thermal step to the protonated 13-*cis* form (Oesterhelt, Meentzen, and Schumann, *Eur. J. Biochem.*, **40**, 453; 1973; Oesterhelt and Stoeckenius, *Proc. natn. Acad. Sci.*, *U.S.A.*, **70**, 2853; 1973). The result of this rapid light-driven cycle is the transport of protons across the membrane and the accompanying production of ATP. This protein is now an important tool in the study of energy coupling driven by electrochemical gradients of the type first suggested by R. J. P. Williams (*J. Theoret. Biol.*, **1**, 1; 1961) and P. Mitchell (*Nature*, **191**, 144; 1961).

The three proteins retinochrome, bacteriorhodopsin, and rhodopsin provide an opportunity for comparative studies of the part played by a protein in directing the course of a photochemical reaction. The three light-induced reactions observed are all-*trans* → 11-*cis*, 13-*cis* → all-*trans* and 11-*cis* → all-*trans*, respectively, the last two also involving loss of a proton at some stage. Retinochrome is unique in being able to catalyse, in the presence of light, the isomerisation to the 11-*cis* form of the 9-*cis* and 13-*cis* isomers of retinol as well as the all-*trans*. The quantum efficiency of the reaction is not known in the case of retinochrome but for rhodopsin and bacteriorhodopsin the efficiencies are remarkably high, 0.65–0.7 and 0.79, respectively. This poses the interesting question of how the protein can direct a photochemical reaction so efficiently along various reaction coordinates or, indeed, in opposite directions along the same coordinate.

Catalysis of an excited state reaction must overcome the fact that non-radiative decay by vibrational relaxation to the ground state can be very fast, $\sim 10^{11}$–10^{12} s^{-1}. In order to become efficient the required photoreaction must be faster than these competing processes. It was therefore not wholly surprising that measurements of the rise time of the earliest detectable intermediate at 560 nm after photolysis of bovine rhodopsin gave a value of less than 6 ps, the experimental resolution. This was taken as evidence that the intermediate, pre-lumirhodopsin, is the first product of the primary photoprocess (Busch, Applebury, Lamola and Rentzepis, *Proc. natn. Acad. Sci. U.S.A.*, **69**, 2802; 1972). It was however recognised by these authors that the nature of a primary photoprocess occurring within $\sim 10^{-12}$ s is severely constrained. Complete *cis–trans* isomerisation is unlikely to take place within this time. These workers suggested on the basis of a recent crystal structure analysis of 11-*cis* retinal (Gilardi, Karle and Karle, *Acta Cryst.*, **B28**, 2605; 1972) that the conformational change involves only a rotation of the central portion of the chain from the 11-*cis*, 12-s-*cis* form to 11-*trans*, 12-s-*cis*.

If it is generally true that unimolecular photoreactions must have a very fast primary step in order to reach high quantum efficiencies, then it is interesting to ask what are the likely primary photoreactions of other polyene–protein complexes. The overall reaction of bacteriorhodopsin involves an isomerisation step and proton loss, as does that of rhodopsin. Which process is the primary fast step? In both proteins a number of intermediates have been identified by their spectral properties either by freezing out at low temperatures or by use of fast detection techniques (Lozier and Stoeckenius, *Fedn Proc.*, **33**, 1408; 1974: Slifkin and Caplan, *Nature*, **253**, 56; 1975). The technique used by Slifkin and Caplan is novel, involving the excitation of bacteriorhodopsin membrane with a modulated light source followed by phase-sensitive detection, at the modulation frequency, of changes in the optical absorption of a monitoring beam. No doubt this is a difficult experiment to perform especially with a scattering material. Resonance Raman spectroscopy has provided the first direct observation of the protonated Schiff base linkage and shows that, in bacteriorhodopsin, the native protein contains this grouping whereas the proton is not present in the link after irradiation with light to produce a species absorbing at 412 nm (Lewis, Spoonhower, Bogomolni, Lozier and Stoeckenius, *Proc. natn. Acad. Sci. U.S.A.*, **71**, 4462; 1974). This result corrects an earlier conclusion, also based on Raman data (Mendelsohn, *Nature*, **243**, 22; 1973). The same technique has also been used to show that an early intermediate of rhodopsin, pre-lumirhodopsin, is

protonated (Oseroff and Callendar, *Biochemistry*, **13**, 4243; 1974).

The difficult question to resolve is which species are primary photoproducts leading to a biochemical event and which competing by-products. Since the quantum efficiencies of formation of these species are not known and since the quantum efficiencies of the photobiological processes of rhodopsin and bacteriorhodopsin are less than unity, this question remains open. In view of the function of bacteriorhodopsin it is worth examining the hypothesis that the loss of a proton from the excited Schiff base may be the primary photoprocess. Involving the motion of a proton along the N–H vibrational coordinate this transfer will be exceedingly fast, within the time of a single vibration. All that is required is a change in the basicity of the N atom in the excited state. If this were followed by a slower thermal isomerism of the polyene chain the role of the protein in selecting the course of the isomerism becomes more comprehensible. One possible test of this hypothesis might be made by measuring the quantum efficiencies of the photoprocesses of rhodopsin and bacteriorhodopsin after deuteration of the Schiff base link. A pronounced isotope effect should be seen only if proton transfer is involved in the primary photoprocess.

Globin synthesis: rates and ratios

from Pamela Hamlyn

It has been known for several years that the α and β globin chains of mammalian haemoglobin are synthesised on different polysomes and yet their production is controlled in such a way that nearly equal amounts of each are produced. The means by which these two independent events are synchronised is the subject of some interest for it seems possible that this mechanism may be one of general importance in the control of synthesis of proteins composed of two or more subunits.

Lodish and his co-workers have made several contributions to the study of globin synthesis control and recently Lodish (*Nature*, **251**, 385; 1975) has derived a simple kinetic rate equation for initiation and elongation of polypeptide chains which, although based on α and β globin synthesis, may be applicable to eukaryotes in general. A result of these calculations is the prediction that any reduction in the rate of polypeptide chain initiation will lead to preferential inhibition of translation of mRNAs with lower rate

constants for polypeptide initiation. Lodish has argued that α mRNA has a lower initiation constant than β mRNA. Based on the observation that α mRNA is found in polysomes averaging three ribosomes, whereas β mRNA polysomes have five ribosomes on average, he contends that since the rate of elongation is the same for α and β chains then α mRNA must initiate protein synthesis only 60% as often as β mRNA. (He suggests that balanced synthesis of the two globins is achieved by a 1.7-fold excess of α mRNA over β mRNA.) Globin synthesis, therefore, provides an experimental situation to test the predictions of his model. Accordingly Lodish has added inhibitors of protein synthesis initiation to a reticulocyte lysate and measured the effect on the ratio of α and β globin synthesised. In all cases he found that it was α mRNA translation that was preferentially inhibited as predicted by his model.

McKeehan, working at the Basel Institute for Immunology, has reported the results of a systematic study of globin synthesis in the reticulocyte lysate in which each of the components of the synthesis was varied in turn—keeping the others constant—and the effect on the α/β globin ratio measured (*J. biol. Chem.*, **249**, 6517; 1974). He found that increasing the concentration of globin mRNA resulted in a decrease in the α/β globin ratio, whereas increasing the concentration of 'initiation factors' (obtained from a salt wash of the small ribosomal subunit), or the concentration of the ribosomal subunits, resulted in an increase in the α/β globin ratio. When experiments were performed with separated subunits it was found that increasing the 40S subunit relative to the 60S gave an increase in the α/β globin ratio, whereas when the 60S subunit was in excess then there was a small decrease in the α/β globin ratio.

McKeehan maintains that these results can best be explained using Lodish's assumptions, namely that β globin mRNA initiates the synthesis of protein more efficiently than α mRNA, and also that there is more active α mRNA than β mRNA bound to polysomes.

Consider for example when the concentration of 40S ribosomal subunit is increased, all other components being held constant. The excess of small subunit means that α and β mRNA are no longer in competition for initiation so that the superior efficiency of β mRNA initiation is not involved in determining the α/β globin ratio produced in the reticulocyte lysate. Only the relative concentrations of the two messengers is effective in determining the globin ratio and since there is more α mRNA then the α/β globin ratio

increases, as is observed experimentally.

Both Lodish and McKeehan make the point that these mechanisms for altering the ratio of α/β globin synthesised rely only on varying the relative amounts of the components of protein synthesis and do not require existence of α and β mRNA specific initiation factors.

The results and predictions of Lodish and McKeehan go some way to defining the components in the mechanism of control of globin synthesis but do not explain how the feedback could operate *in vivo*. In other words, adding more 9S RNA to the constituents of protein synthesis may increase the relative amount of β globin but how is the lack of β globin communicated so that more 9S mRNA is made available to the ribosomes?

rosy structural gene for xanthine dehydrogenase

from Benjamin Lewin

WHAT is a gene? This question has been resurrected by the present debate on the nature of the unit of gene expression in eukaryotes. At the heart of the discussion is the apparent discrepancy between the coding potential of the eukaryotic genome and its probable number of genes. This can be placed on a satisfactory quantitative basis really only with *Drosophila*, where a visible division of the genetic material into about 5,000 bands is evident in the polytene chromosomes of the salivary glands. That each band represents a single genetic function is suggested by the identification of individual lethal complementation groups with single bands in a region of the X chromosome (Judd, Shen and Kaufman, *Genetics*, **71**, 139–156; 1972) and by the rough equality between the total number of sex-linked lethals and X chromosome bands (Hochman, *Cold Spring Harb. Symp. quant. Biol.*, **38**, 581–598; 1973) and between the total number of third chromosome late lethals and bands (Shearn, *Genetics*, **77**, 115–126; 1974). But the average content of a band is about 30,000 base pairs, sufficient to code for 10–20 proteins of average size. Two extreme views can be taken of this situation: all genes may be identifiable by lethal mutations, so that each band contains only one protein-coding sequence, on average occupying about 10% of the DNA; or only a small minority of genes can be identified by lethal mutation, so that there may be many 'null loci' that are unidentifiable by mutation, in which case there might

be some 50,000 genes with many in each band (see Lewin, *Nature,* **251,** 373–375; 1974).

Another approach to defining the genetic unit is to determine the nature of mutations at some locus. The mutations mapping in one complementation group may include *cis*-dominant control elements as well as structural genes; since most loci are identified by the effects which mutations in them have upon the phenotype, there

is usually no way to tell whether they represent alterations in a control element or structural gene. To determine the class of mutational event therefore demands analysis of loci where a phenotypic effect can be recognised and the protein product is known.

rosy mutants in *Drosophila* have eyes that are brownish in colour (instead of the wild type red colour). Two sets of observations suggest that this locus is connected with the enzyme xanthine

dehydrogenase. A dosage effect exists in which heterozygotes with only one ry^+ gene possess half of the wild type level of enzyme activity; and abnormal flies with three ry^+ genes have 150% of the wild type level (Grell, *Z. Vererb.,* **93,** 371–377; 1962). This could mean that *rosy* mutations act in a control element to prevent synthesis of XDH or that they represent alterations in the structural gene completely preventing enzyme activity. Isoalleles that affect the electrophoretic mobility of XDH (but which are wild type in eye colour) map close to the *rosy* mutations, an indication that the structural gene is in or close to the *rosy* locus (Yen and Glassman, *Genetics,* **52,** 977–981; 1965). By fine mapping of some of these isoalleles, Gelbert, McCarron, Pandey and Chovnick (*Genetics,* **78,** 869–886; 1974) now define their relationship to *rosy* mutations in a report on the organisation of this locus.

rosy mutants entirely lack XDH activity, since even low levels of this enzyme are sufficient to allow expression of the ry^+ phenotype, so that it is the ry^+ isoalleles alone that can be used to define the structural gene by their effect on the mobility of the enzyme. Since it is not practical to map such sites directly, the first step in this analysis was to derive *rosy* mutants from each of five of the ry^+ isoalleles. When two such *rosy* mutants are crossed, ry^+ progeny can be selected by growth on a purine-supplemented medium which kills larvae lacking XDH. In these experiments, 170 ry^+ survivors were obtained from a total of 7×10^6 zygotes. The markers present on either side of the *rosy* locus were used to determine whether a crossover or gene conversion event was responsible for generating the ry^+ progeny. Examination of these strains to determine whether they have the XDH electrophoretic mobility characteristic of the maternal or paternal parent can then be used to map the site responsible for the electrophoretic variation. In effect, the *ry* mutant sites are selected markers in these crosses and the sites responsible for electrophoretic mobility comprise unselected markers.

The electrophoretic (*e*) sites mapped in two clusters, one at each end of the region identified by *rosy* mutations. This leaves open the possibility that the structural information for XDH might be located in two elements separated by some distance. By using a *cis/trans* test, however, Gelbart *et al.* demonstrated that *e* sites at both extremes appear to fall within the same protein-coding element. This is consistent with the observation that the enzyme XDH consists of a dimer of two identical subunits of about 130,000 daltons; this should require a coding length of a little more than 3,000 base

Strong interactions of the psi

from David J. Miller

SINCE the ψ (or J) particles were first discovered at Brookhaven and the Stanford Linear Accelerator Centre in November 1974 (see *Nature,* **252,** 438; 1974 and *Phys. Rev. Lett.,* **33,** 1404, 1406 and 1408; 1974), experimental physicists all over the world have been looking for their effects. Some have scanned the data already collected from previous experiments, others have made proposals for new and more refined experiments, but much of the data now appearing is coming from apparatus which just happens to be set up at the accelerators or storage rings, and which has been rapidly adapted to look for the new particles.

The world of physics has been swept by waves of gossip, often inaccurate, and it has become necessary to separate 'mezzofacts' from real facts which can be reliably traced back to their authors.

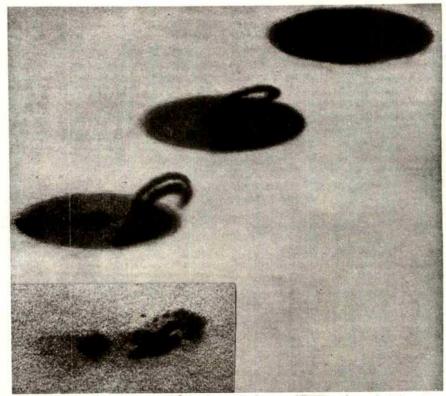
The latest pieces of information to leave the mezzo-fact category are data on the photoproduction of the ψ (or J) with a mass of 3.1 GeV/c^2. The Brookhaven experiment showed that this ψ is produced with a very low probability in proton–proton collisions. The SLAC, and other subsequent e^+e^- experiments, saw copious production. These two results implied that the ψ takes part in electromagnetic interactions, but might not have strong interactions with nucleons (protons or neutrons). In photoproduction, a particle is produced by bombarding a nuclear target with high-energy γ rays. If the ψ is a 'vector' particle, like the φ meson (as discussed in *Nature,* **252,** 438; 1974), then an interacting photon could sometimes behave as if it were an incoming ψ. The photoproduction of the φ, and the related ρ and ω vector mesons, are very well explained by treating the incoming photon as a vector meson, which then has a strong interaction with the target nucleon. This is called the 'vector meson dominance model'

(VMD) of photon–hadron couplings. If the ψ is a hadron (a strongly interacting particle) then the model would predict the rate of ψ photoproduction, with only two important parameters: the strength of the coupling of γ to ψ, which is measured directly by the $e^+e^- \to \psi$ experiments, and the cross section (a direct measure of probability) for ψ–nucleon scattering.

Three groups have produced results in searches for ψ photoproduction. At the Cornell electron synchrotron (*Phys. Rev. Lett.,* **34,** 231; 1975) no sign of ψ production has been seen with 11 GeV photons. An experiment at the SLAC linear accelerator has also seen no ψ production from 18 GeV photons (*Phys. Rev. Lett.,* **34,** 288; 1975). But news has come from the Fermi National Accelerator Laboratory near Chicago that a group led by Professor Wonyong Lee of Columbia University has seen ψ photoproduction by photons of about 100 GeV produced from the 400 GeV proton-synchrotron. This result was a mezzo-fact for some months, but has now been reported by Lee himself in an FNAL seminar and can be regarded as authentic.

The tentative rate for ψ photoproduction at FNAL appears consistent with the limits put upon it by the two experiments which saw no effect. Using the VMD model it is clear that Lee's result implies a cross section for ψ–nucleon collisions somewhere in the region of one millibarn (10^{-26} cm^2). Only the strong interaction could give such a large cross section, but the cross sections of other strongly interacting particles are all in the region of 20 to 40 millibarns. The ψ therefore seems to be a 'semi-strong' particle. It is likely that this inhibited interaction probability is linked to the narrow width of the ψ and slowness of its decays, but there is no agreement on what the link may be.

airs. This length fits well with the enetic analysis of *rosy*, since *ry* iutants span 9×10^{-3} recombination nits, and 0.01 units has been estimated o represent almost 4×10^3 base pairs. he *rosy* locus lies in a region of five ands on the polytene third chromo- ome and since these are of average ze this implies that whichever band ontains *rosy* has about ten times more)NA than codes for the protein. The *osy* site, lying at map position 52.0, is ounded by *kar* at position 51.7 on one ide and by *l(3)26* at position 52.2 on he other and the isolation of further iutations may, of course, permit a iore exact resolution of its extent.

If it is true that the distribution of iutant sites within control elements nd structural genes directly reflects ieir relative sizes, these results show hat the *rosy* locus represents a struc- ural gene; for if only part of the egion identified by *rosy* mutations had he function of coding for protein, the ites responsible for electrophoretic ariation would lie in one small cluster nstead of extending to both ends of he genetic map. In support of this ontention, Gelbart *et al.* argue that he *rosy* mutations which they selected y X-ray mutagenesis largely represent ingle base pair alterations. Point nutations in this case must be able to bolish completely the activity of XDH. ly using mutagens inducing other types f changes that perhaps might be prone o have effects on control elements, in he future it may be possible to identify egulatory *rosy* mutations. The conclu- ions that the *rosy* locus is largely iccupied by the structural gene for <DH depends also upon the assumption hat recombination rates are constant ier unit length of DNA throughout ioth control element and structural ;ene; for if recombination takes place it a greater frequency in the structural ;ene than in the control element, the ipparent size of the structural gene vould be exaggerated relative to the iontrol element. The failure of Chov- iick and his colleagues to observe inequal crossing over in their earlier xtensive analysis of recombination at he *rosy* locus argues that the structural ;ene itself comprises nonrepetitive)NA, but leaves open the possibility now under study) that adjacent control iements might represent repetitive equences in which recombination is iuppressed in order to limit such events. he most probable explanation of these esults therefore seems that the *rosy* icus represents the structural gene for <DH, occupying only some 10% of the and in which it is located. Whether the emaining DNA represents control inctions associated with the XDH iructural gene and thus defines a single enetic unit remains a point for future esearch.


Ring galaxies and intergalactic gas clouds

from Craig D. Mackay

IN a recent article in *The Astrophy- sical Journal* (**194**, 569; 1974), Freeman and de Vaucouleurs attempt to account for the formation of two types of object usually dismissed as "irregular galaxies". The first appears as an ir- regular ring of gas with a number of condensations within it, the second (an example is shown at the bottom of the accompanying figure) appears as a spheroidal galaxy composed almost ex- clusively of stars with a small region filled with several blobs of gas.

The ring galaxies have a number of features similar to those of the annulus of gas found in many spiral galaxies. Freeman and de Vaucouleurs con- sider the possibility that such an annulus was stripped out of a normal spiral galaxy to form a ring galaxy by a collision with an intergalactic gas cloud. The presence of large clouds of neutral or ionised gas moving within clusters of galaxies has been suggested as a convenient way of stabilising clusters of galaxies. The scenario proposed is as follows: Suppose that a gas cloud collides with a normal spiral galaxy as is shown in the artist's impression in the upper part of the figure. Stars, being small and massive, are not affected by the colliding gas cloud. The annulus of gas, however, is

progressively stripped out of the galaxy as shown in the figure. Some of this gas may be attracted back towards the massive disk of the galaxy, giving rise to the 'hook' in the lowest of the artist's sketches, a sketch which looks remarkably like the object NGC 7828–29 shown at the bottom of the figure. Eventually all the gas is swept out of the galaxy and a spinning ring of gas is formed moving away from the parent galaxy. This gas ring is unstable and expands (because of the unbalanced centrifugal force) until it is braked by the background gas in the cluster. On fairly short time scales ($\sim 10^8$ years) in- stabilities in the gas cause knots to condense in the ring giving structures very similar to the ring galaxies ob- served.

The main difficulty with Freeman's and de Vaucouleur's model is that it is important the collision happens rapidly enough to ensure that all the gas is swept out in a small fraction of the rotation time of the galaxy (otherwise the ring structure will become grossly distorted). A second problem is that it is difficult to avoid heating the gas ring in such a collision to an extent that the ring structure is completely disrupted. There is, however, no doubt that their model gives a compelling account of the formation of these hitherto un- explained galaxies. Indeed, the elegance of their model ensures that it will receive further serious attention and may help to explain a number of the many other unusual galaxies which are all around us.

Artist's conception (above) of three typical phases of penetration of disk galaxy passing through an intergalactic cloud, with progressive separation of gas annulus from disk; (bottom) photograph of NGC7828–29.

Seismic activity before earthquakes

from Peter J. Smith

IT is now well known that many moderate and large earthquakes are immediately preceded by smaller foreshocks; that is, over periods ranging from weeks to hours before significant seismic events there is an increase in seismic activity. But what happens to the seismicity in the vicinity of an earthquake epicentre during the preceding months and years? Here opinions are more divided, with some studies concluding that the level of regional seismicity also generally increases over the longer time scale and others suggesting that earthquakes are frequently heralded by a period of relative quiescence.

Mogi (*Bull. Earthquake Res. Inst.*, **47**, 395; 1969), for example, concluded from a study of four great Japanese earthquakes that whereas the immediate epicentral area becomes relatively calm for some years prior to the main shock, activity in the surrounding regions increases markedly. He likened the pattern of seismicity to the shape of a ring doughnut centred on the epicentre. A somewhat similar pattern was also observed by Borovik *et al.* (*Izv. Acad. Sci. USSR, Phys. Solid Earth*, **2**, 21; 1971) in a quite different tectonic setting. Borovik and his colleagues found that the area surrounding the 1959 Baykal (Soviet Union) earthquake was relatively quiet seismically for several years before the event and that the quiet area, or 'preparation region', enclosed the aftershock zone. During the 7½ years preceding the main earthquake, only two (smaller) earthquakes were observed within the preparation region whereas 20 were recorded in an outer region of comparable area. After examining the geological structure and seismicity of southern California, Allen *et al.* (*Bull. Seismol. Soc. Amer.*, **55**, 753; 1965) even went so far as to propose that areas of seismic quiescence may indicate the sites of future large earthquakes.

Fedotov *et al.* (in *Earthquakes and the Deep Structure of the South Kurile Island Arc*, Moscow, 1969) have taken precisely the opposite view, arguing from their study of the Kamchatka–Kurile–Japan seismic zones that impending great earthquakes are heralded by an increase in seismic activity beginning 5–20 years before. In this they are supported by Sadovsky *et al.* (*Tectonophysics*, **14**, 295; 1972) who suggested on the basis of Asian studies that an increase in seismic activity over a 5–10 year period indicates a forthcoming strong earthquake. Suyehiro and Sekiya (*Tectonophysics*, **14**, 219;

1972) also found that the seismicity in the vicinity of the great Kanto earthquake of 1923 was significantly greater during the few years before the shock than over the period 1926–1972. And finally, Tocher (in *San Francisco Earthquakes of March 1957*, California Division of Mines and Geology, Spec. Rep. 57, 1959) concluded that for several decades preceding the Hayward earthquake of 1868 and the San Francisco earthquake of 1906 moderate earthquakes probably occurred at a greater frequency than they do on average over the longer term. He thus interpreted increasing regional seismicity as a symptom of a strain buildup which could subsequently lead to a major shock.

So which side is right? Or is the conflict more apparent than real, either because different earthquakes are associated with genuinely different precursory phenomena or because experimental and analytical techniques have hitherto been imperfect? In an attempt to resolve the matter, Kelleher and Savino (*J. Geophys. Res.*, **80**, 260; 1975) have now carried out an extensive study of the patterns of seismic activity preceding large strike-slip and thrust-type earthquakes which have occurred along the northern, northwestern and eastern margins of the Pacific. The events include the San Francisco earthquake of 1906, the Kamchatka event of 1952, the Chile shock of 1960, the great Alaska earthquake of 1964 and several others, most of which had rupture zones extending hundreds of kilometres. In each case the foci of all shallow (<100 km) events preceding the main shocks were relocated, in some cases for precursory intervals of up to 45 years.

The observed patterns of seismicity preceding large earthquakes were found to correlate with the configurations of the shocks' rupture zones and with the positions of the main event epicentres within the zones. Specifically, extensive parts of the rupture zones were relatively aseismic until the times of the main shocks, and the low levels of seismicity applied to events at least several magnitudes smaller than the main shocks and probably to events many magnitudes smaller. On the face of it, this would seem to support those arguing for precursory quiescence; in practice, the detailed picture looks rather different. In most of the earthquakes examined by Kelleher and Savino rupture began in an area of moderate seismic activity, propagated up to hundreds of kilometres into adjacent quiet regions, and in many cases ended in areas with marked prior seismicity. Thus prior seismic activity often occurred near the epicentres of the main events and near the edges of the rupture zones but not throughout

the main bodies of the zones.

These general principles are w illustrated by the Kamchatka eart quake of 6 November 1952. During t earthquake, rupture propagated fro the focus towards the south-we parallel to the strike of the thrust pla and throughout an elongated zone 40 500 km long and 100–200 km wi For 30 years before the earthqual most of the rupture zone was relative quiet seismically; but throughout t period there was a clustering of activ around the position of the subseque epicentre at the north-east of the ru ture zone and around the oppos (south-western) end of the zone. T bulk of the rupture zone only becar seismically active with the aftershoc of the main earthquake.

There is some indication from t Kamchatka and other large eart quakes that, where prior activity dc occur (especially in the epicentr regions), its level increases as the ma shock approaches. On the one han there is no suggestion that precurso seismic activity appears in the ga where none occurred before. Gaps seismicity for great earthquakes alor major plate boundaries seem to gaps for smaller magnitude activi also; and these gaps remain until a unless they become aftershock zone Unfortunately, the available data a insufficient to enable temporal var tions to be determined in any gre detail. Thus it is not yet possible to sa whether a seismic gap becomes quie cent as part of a definite process leadi to a large earthquake or whether, on the aftershocks of a large event ha died away, the gap remains quiesce until the next large shock. At prese there are data to support either b haviour but not enough to deci which predominates. What the ne study by Kelleher and Savino has mac clear, however, is that the spatial di tribution of seismicity is critical in an attempt to describe temporal vari tions. It is not enough to say that particular earthquake was preceded t relative quiescence or a regional i crease in the level of seismic activit The precise points at which thes phenomena do or do not take plac must be clearly determined.

from Angela Vincent

THE transmission of impulses at th neuromuscular junction is achieved b the release of acetylcholine from th nerve ending. Acetylcholine interac with receptors on the endplate of th muscle and causes a change in sodiu and potassium permeability whic

results in propagation of the impulse along the muscle fibres and activation of the contractile apparatus In mammalian skeletal muscle the endplate has a diameter of 20–60 μm, but its surface area is increased by infolding of the postsynaptic membrane The acetylcholine receptor in normal muscle is confined almost exclusively to the endplate, as has been shown autoradiographically by labelling with the specific and irreversible blocking agent α-bungarotoxin (α-Bgt) (Lee, Tseng and Chiu, *Nature*, **215**, 1177, 1967, Barnard *t al*, *Nature*, **234**, 207, 1971) Recent estimates of receptor sites suggest a density of $2–4 \times 10^4 \mu m^{-2}$ (Fertuck and Salpeter, *Proc natn Acad Sci U S A*, **1**, 1376, 1974, Porter and Barnard, *J Membrane Biol*, **20**, 31, 1975) When the nerve to a muscle is cut, acetylcholine sensitivity begins to appear over the entire surface of the muscle fibre and reaches a maximum in 2–3 weeks, only declining as reinnervation takes place (Axelsson and Thesleff, *J Physiol*, *Lond*, **147**, 178, 1959, Miledi, *Physiol*, *Lond*, **151**, 241, 1960) Radioactively labelled α-Bgt binding gain follows this closely binding increases 20-fold overall (Miledi and Potter, *Nature*, **233**, 599, 1971), but the density of extrajunctional sites, at peak 600 μm^{-2} (Fambrough, *J gen Physiol*, **4**, 468, 1974), never approaches that at the endplate itself Despite the translation freedom found for many membrane-bound proteins the normal endplate receptors remain discretely localised—even after denervation and degeneration of the nerve ending

What makes the endplate so stable? Berg and Hall (*Science*, **184**, 473, 1974) labelled rat denervated diaphragm with ^{125}I-α-Bgt *in vivo*, removed the muscles and cultured them for 24 hours They found that the extrajunctional radioactivity declined with a half life of 8 h, whereas there was only a marginal reduction in endplate labelling during that time The rate of ^{125}I loss was reduced considerably by metabolic or protein synthesis inhibitors, indicating that little of it was due to reversibility of the toxin–receptor complex Radioactivity recovered from the medium as mostly degraded toxin, although native toxin added to the culture was not broken down They concluded that the extrajunctional toxin–receptor complex was being metabolised considerably faster than the endplate complex Chang and Huang (*Nature*, **253**, 43, 1975) confirmed these findings, but they left the ^{3}H-α-Bgt-labelled diaphragms *in situ* for several days before removing them They found that the turnover of endplate receptors had a half life of about 7 5 days which could be shortened by conditions which are known to increase the synthesis of new receptor, such as denervation per-

formed at the same time as labelling Their value for the half life of extrajunctional receptors in rats denervated 9 days previously was 19 hours, somewhat longer than Berg and Hall found in rats which had been denervated 5 days previously

Does this different turnover reflect differences in the receptor molecules themselves, or in their mode of incorporation into the membrane? Several reports suggest that the two classes of receptor in intact muscle are not identical—with respect to their sensitivity to cholinergic antagonists (Beranek and Vyskocil, *J Physiol*, *Lond*, **188**, 53, 1967 and Lapa *et al*, *Exp Neurol*, **43**, 375, 1974) and their acetyl-

A hundred years ago

The third paper was by Mr B Tower, on a method of obtaining motive power from wave motion He said that this inquiry originated with Mr Deverell, who came home from the antipodes for the purpose of promulgating it Mr Deverell's proposition was to suspend a heavy weight on board a ship by means of springs, and to obtain motive power by the oscillation of this weight through a distance not more than the height of the waves It however appeared to Mr Tower that since the centrifugal force of wave motion in a vertical direction is alternately added to and subtracted from, the force of gravity thereby causing a virtual variation of the intensity of that force, the question might be broadly stated as follows —

Supposing the force of gravity to vary in intensity at regular intervals, that is, to become alternately greater and less than its normal amount, what is the best means to obtain the maximum amount of energy from a given weight oscillating under the influence of these variations?

Now as energy or power is defined as force moving through distance, it is clear that the quantity of energy or power to be obtained by this system will depend on the distance through which this weight is caused to move during each successive variation of gravity

The first experiments Mr Tower made with a model apparatus constructed on these principles showed him that the best arrangement would be to put a weight on the end of a revolving arm, whereby the centrifugal force of the wave motion might be utilised as well as the rising and falling motion

from *Nature*, **11**, 410, March 25, 1875

choline noise spectra (Katz and Miledi, *J Physiol*, *Lond*, **224**, 665, 1972) On the other hand, using detergent-solubilised receptors, Chiu *et al* (*Biochem Biophys Res Commun*, **51**, 205, 1973) showed that both receptors had the same apparent molecular weight on gel filtration, and Alper *et al* (*FEBS Lett* **48**, 130, 1974) found very similar 'protection constants' for several cholinergic ligands with respect to α-Bgt binding

Many of the α-Bgt binding studies have been done on the intact rat diaphragm but this has certain disadvantages since one is dealing with a slowly diffusing polypeptide which makes kinetic analysis difficult In *Biochemistry* (**13**, 5522, 1974), Almon, Andrew and Appel report some interesting results with Triton-solubilised receptors from rat leg muscles They show ^{125}I-α-Bgt binding isotherms for normal and denervation-induced receptors In both cases they find that the binding follows that predicted for a homogenous ligand interacting with a single class of independent sites They find, however, that the toxin has a 10-fold higher affinity constant in denervated muscle extracts More important, prolonged exposure to 1% Triton X-100 changes the toxin's affinity for the normal receptors to that found for the extrajunctional ones, although the number of sites remains the same

Until now, the separate purification of the two types of muscle receptor has seemed a formidable task, because of the very low yield obtainable from normal muscle Nevertheless, in the Abstracts of the Biophysical Society (*Biophys J*, **15**, 332a, 1975) Brockes and Hall report the purification, by affinity chromatography, of normal and denervation-induced receptors from rat diaphragm Apparently, the two receptors are both glycoproteins and indistinguishable on gel-filtration and zone centrifugation But they do exhibit some differences in affinity for α-Bgt and sensitivity to D-tubocurarine, and show separate peaks on isoelectric focusing

At present it looks as if the normal and denervation-induced receptors are not very different, at least in macromolecular terms The very high density of receptors on the postsynaptic endplate membrane makes interactions between them seem a possible explanation for the lower rate of turnover and other differences observed *in situ* There is, however, no evidence that the solubilised endplate receptors are aggregates of the less densely packed extrajunctional ones On the contrary, the results of Almon *et al* suggest that other hydrophobic components could interact with the receptors in the membrane-bound state, and survive to some extent in mixed Triton micelles on

solubilisation In this context it is interesting that Fambrough (*Neurochemistry of Cholinergic Receptors*, edit by E de Robertis, Raven Press, New York) observed that clusters of toxin-labelled receptors on cultured chick muscle cells could be dispersed by 0 01% Triton, although this treatment did not solubilise the receptors or irreversibly damage the membrane

It seems that to establish the membrane characteristics which are responsible for the stability of the endplate it will be necessary not only to investigate the structure of the receptor protein itself, but also to look more closely at the involvement of other membrane components in the intact tissue

Conservation of nitrogen in climax ecosystems

from Peter D Moore

CLIMAX ecosystems possess several attributes which lead to an increased conservation of essential nutrients, for example, nutrients generally become concentrated in the biota, and nutrient output from the system is low in comparison to this biotic reservoir (Bormann, Likens and Eaton, *Bioscience*, **19**, 600, 1969) In a series of papers, Rice and Pancholy (*Am J Bot*, **59**, 1033, 1972 and **60**, 691, 1973) have now suggested that certain climax vegetation types may inhibit nitrification by soil microbes, as a result of the production of toxins in the litter, thus reducing the rate of nitrate production and loss

In the process of nitrification ammonium ions are oxidised by microbes in two stages to nitrite and then to nitrate, in which form nitrogen is more readily available to the majority of plants In this form, however, nitrogen is easily lost from ecosystems since, being anionic, it is not retained well by clay colloids in the soil Rice and Pancholy therefore regard the suppression of nitrification as a mechanism whereby nitrogen is retained within the ecosystem

They were led to this position initially by a number of reports concerning grassland habitats in which low activities of the nitrifying bacteria and very low nitrate levels were found Theron (*J Agric Sci, Cambs*, **41**, 289, 1951) had suggested that grass roots could secrete a toxin which might affect nitrification and, in African grasslands, Boughey *et al* (*Nature*, **203**, 1302, 1964) suggested that the secretion of toxic substances by the grass *Hyparrhenia* could explain many aspects of the ecology of these habitats Rice and

Pancholy followed up these ideas in an old field succession in Oklahoma by measuring ammonium and nitrate levels in soils from various stages in the succession

They showed high nitrate levels in the early stages falling to low levels at the climax, with ammonium ions behaving in a reciprocal fashion They also found that the density of *Nitrosomonas* and *Nitrobacter* (the nitrifying bacteria) in the soil fell during the course of succession In 1973 they published further data implicating tannins and their derivatives as possible agents in the suppression of nitrification and showed that tannin levels were highest in the climax soils Particularly surprising were the high tannin concentrations in grassland soils and in the litter produced by grasses This, they felt, could account for the low nitrate levels found in many grasslands, particularly since *Nitrosomonas* activity is inhibited by tannin levels of only 2 p p m , less than half the lowest recorded soil concentration in grasslands *Nitrobacter* (which oxidised nitrite to nitrate) was less sensitive, but suppression of one step would effectively block nitrification

Recently (*Am J Bot*, **61**, 1095, 1974) they have attempted the separation and identification of the precise inhibitors which may be involved and, by analysing acetone extracts of plants and soil, have come to the conclusion that many compounds in addition to tannins could be active in suppression, mainly phenolic acids and phenolic glycosides All were more effective in suppressing *Nitrosomonas* than in the inhibition of *Nitrobacter*

Meanwhile, back in the African grasslands, more work has been in progress on the suggested inhibitory properties of *Hyparrhenia*, Purchase (*Plant Soil*, **41**, 527, 1974) has added the washings of this grass to soils and has checked the progress of nitrification After 13 days nitrate production began to fall, but Purchase regards this as the result of increased acidity, since addition of $CaCO_3$ to the water led to continued nitrate production Eluate of the soils seemed not to influence the activity of test *Nitrobacter* cultures, but Rice and Pancholy have shown that the nitrite to nitrate stage of the oxidation is less sensitive to inhibitors Nitrate production was depressed when *Hyparrhenia* root macerate was added to soils, but Purchase puts this down to immobilisation of the mineral nitrogen by the presence of root tissue, since there was no build-up of ammonium ions which one might expect if the nitrifying bacteria were suppressed Purchase considers the scarcity of nitrifying bacteria in *Hyparrhenia* grassland soils to be due to the immobilisation of ammonium ions by root

tissue, hence robbing the microbes of a substrate

Chase, Corke and Robinson (in *The Ecology of Soil Bacteria*, edit by T R G Gray and D Parkinson, 593, Liverpool University Press, 1967) have come to the conclusion that in some soils low pH and phosphate deficiency may limit nitrification Using perfusion techniques they showed that nitrification could be induced in infertile grassland soils, perfused with ammonium sulphate, by the addition of lime and phosphate Purchase (*Plant Soil*, **41**, 541, 1974) has also investigated the possibility that the savanna grassland soils could be deficient in nitrifying bacteria because of low phosphate levels, even when ample ammonium ions are available He added ammonia to soils with varying degrees of phosphate deficiency and found that the nitrification resulting was closely related to the amount of available phosphorus in the soil He concludes that phosphate deficiency in savanna soils could account for the restricted nitrification, the nitrite oxidisers being particularly sensitive It is also possible that the grass roots themselves, together with associated rhizosphere microorganisms, are competing with the nitrifiers for phosphate, thus aggravating the deficiency Robinson (*Plant Soil*, **19**, 173, 1963) has suggested this sort of competition, but for ammonium ions, in New Zealand grasslands

It is now well known that many higher plant species are able to absorb and utilise nitrogen in the form of ammonium ions Recent work by Havill, Lee and Stewart (*New Phytol*, **73**, 1221, 1974) suggests that in some habitats where nitrate production is particularly low, such as acidic, ombrotrophic mires, many of the higher plants have a reduced capacity for nitrate utilisation, since their nitrate reductase activities are very low Such species must depend upon ammonium ions as their major source of nitrogen As Rice and Pancholy have pointed out, this mechanism not only bypasses the microbial nitrification stage, which may reduce the risk of nitrate loss from the ecosystem, but also saves the plant the energy required for the activity of nitrate reductase Whatever the mechanism whereby nitrification is suppressed in some ecosystems, and it is likely that the precise nature of the suppression varies from one ecosystem to another, the resulting nitrate scarcity has evidently placed a selective pressure upon the resident plant species, resulting in their ability to use ammonium ions This evolutionary response and the suppressed nitrification which has engendered it, may well provide a mechanism for ecosystem nitrogen conservation

articles

Geology, fauna and palaeoenvironments of the Ngorora Formation, Kenya Rift Valley

W. W. Bishop & M. H. L. Pickford

Department of Geology, Queen Mary College, London University, Mile End Road, London E1, UK

The Ngorora Formation occurs within a long sequence of stratigraphic units that are firmly calibrated by $^{40}K/^{40}Ar$ dates It contains an impressive fauna and has yielded a valuable amount of information on local palaeoenvironments and on the sedimentary processes operative during its deposition Here, a previously unpublished vertebrate and invertebrate faunal assemblage between 9 and 12 Myr old is recorded, and the stratigraphic framework of this former gap in the fossil mammalian record of Africa south of the Sahara is described

RESEARCH on the Ngorora Formation[1-7] has produced a detailed but as yet incomplete picture of the palaeoenvironments and fauna Key marker horizons have been traced from area to area, detailed measurements have been made of numerous well exposed sections and facies variations have been recognised over a large area Of particular faunal interest are the collections of Equidae, Hippopotamidae, Orycteropodidae, Hyaenidae, Hyracoidea, Gomphotheriidae and Canidae Antlered ruminants similar to forms from Fort Ternan have been found, and remains of a small listriodont suid are relatively common

Palaeogeomorphological setting

The Ngorora Formation was deposited in a basin floored by rocks of the Tiim Phonolites Formation, and was limited to the west by the Elgeyo Escarpment, to the east by a rise towards the area of the present Laikipia Plateau and to the north by the uplands round the Tiati volcanic centre To the south, the boundary was controlled by the rise of the rift floor, in a similar way as at present (Fig 1) The basin was tectonically active before, during and after the deposition of the Ngorora sediments The principal structural trends within the basin are exhibited by escarpments along the Kito Pass, Saimo, Cherial and Kaption faults

The Saimo Horst was a topographic high during most of Ngorora times and underwent contemporaneous weathering and erosion for at least part of the time The sediments thin rapidly north-eastwards towards Sidekh, which was also a strong positive element in the topography and is unlikely to have been completely covered by sediment or water during the deposition of the Ngorora Formation

These two upland areas were separated by about 8 km of low lying country near Bartabwa (C5, Fig 2) which was mantled by an extensive cover of sediments (Fig 2) The Ngorora Basin may be divided into three areas on the basis of the types of sediment they contain (Fig 1) Area I, which lies to the north of the Saimo Horst, comprises two subdivisions The first is the type area of Kabarsero (area I*a*)

lying to the east of the Kito Pass Fault The second area lies on the western, upthrow side of the fault, where the sequence is thinner (area I*b*) Area II comprises and the slope of the Tugen Hills west of the Cherial Fault and contains the Kapkiamu Graben and the Kaption Volcanic Complex Area III lies to the south of the Saimo Horst and contains the upper part of the Ngorora succession lying on a deeply weathered surface of Tiim Phonolite Correlations between the three areas must remain tentative because of lack of continuity of outcrop between them and the absence of marker horizons common to them all

Stratigraphy

The thickness of the Ngorora Formation varies greatly in different parts of the basin At Kabarsero, the type area, the sediments are 400 m thick whereas in area I*b*, at Kalimale they are 215 m thick (Fig 3) The formation thins rapidly north-eastwards from Kalimale (C6, Fig 2) and pinches out below the summit of Sidekh In the south, in area III, only the upper parts of the formation are present, and these thin southwards and pinch out at about 0°30'N

Bishop and Chapman[1] divided the formation into five units which are here ranked as members (Fig 3) The lowest unit, member A, consists in area I of thick beds of coarse volcaniclastic sediments and clays Some of the beds originated as lahars, possibly from the Kaption Volcano, lying in area II to the south-west

Member B consists of alternating, current bedded, gritty tuffaceous beds, clays and silts An accretionary lapilli tuff in area I may be correlated tentatively with a very thick unit of similar lithology in area II On the upthrow side of the Kito Pass Fault (area I*b*) the clays and silts found in the type area are absent and beds of sandy and gritty tuffs lie directly on top of one another

In area I*a*, member C is composed of finely laminated clays and shales with occasional sand grade beds intercalated On the upthrow side of the Kito Pass Fault (area I*b*) the latter part of member C is cut out by slight erosion and channelling In area II over 200 m of alternating shales and laminated clays are found in the Kapkiamu Graben The shales consist almost entirely of chemical precipitates, and the clays were probably produced largely by weathering of the Tiim Phonolites In area III an unknown thickness of diatomaceous suncracked shales overlies a weathered surface of Tiim Phonolites, but it is not known whether these are the lateral equivalent of member C

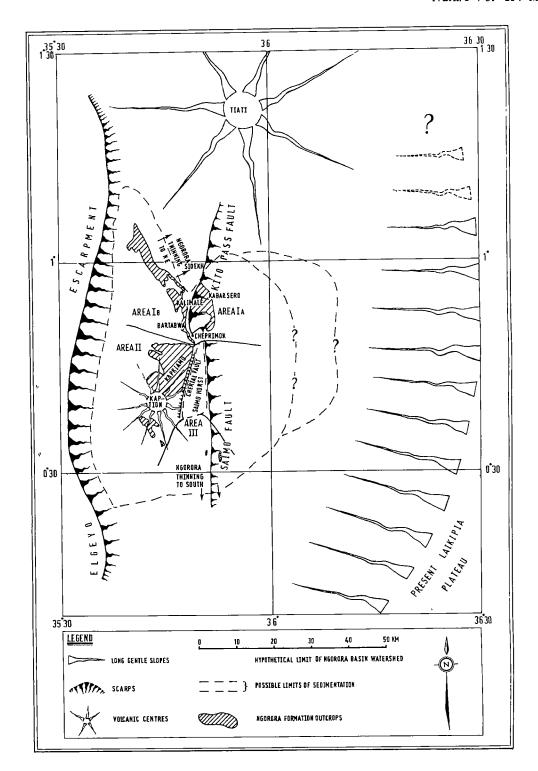
In areas I and II, member D is a succession of clays rhythmically alternating with cross-bedded silty and gritty tuffaceous beds Earth movements during the deposition of member D are indicated by slumps, faults and fissures which do not affect the overlying units At Cheprimok (C5, Fig 2) major faulting resulted in the erosion of nearly 130 m of


Fig 1 Regional setting and outcrops of the Ngorora Formation

sediment so that member E rests unconformably on member A and oversteps on to Tiim Phonolite This faulting episode was widespread and has been recognised in area II, 20 km away In area III a series of red marly earths and silts may be the lateral equivalent of member D

Member E sediments were deposited after another major faulting episode which lowered the base level to such an extent that lacustrine conditions were established again A series of diatomaceous and fish-bearing shales is widespread over the whole of area I and parts of area II, but erosion has removed much of the record The erosion was consequent on movement on the Kito Pass and Saimo Faults which uplifted the crest of the Tugen Hills tilt block until it was exposed to subaerial processes Area Ia, on the down-

throw side of the faults, underwent further sedimentation but the changed environment resulted in the deposition of coarse material including conglomerates, rather than the deposition of shales like those found in the lower part of the sequence In area III, a series of conglomerates and bedded tuffs may be equivalent to member E In every area an erosional unconformity separates member E from the overlying Ewalel Phonolite Formation

Figure 3 illustrates stratigraphic sections from areas Ia and Ib respectively, to show variation in thicknesses of the different members Several important horizons can be traced across the Kito Pass Fault and reveal thickness changes indicating contemporary fault movement throughout the deposition of the sequence The units on the upthrow side

f the fault are usually condensed sequences, whereas
1ose on the downthrow side often contain extra units of
ays and silts

Sediments are derived from several sources The Kaption
olcano in area II probably supplied many of the lahars
1d much of the tuffaceous material found in area I Some
diment was derived from the Laikipia area and also from
e Tiati volcanic centre The laminated clays of the
apkiamu Graben may have been derived from phonolite
eathering products on Saimo Horst

The Saimo Horst and Sidekh tilt block acted as barriers
sediment derived from the east, although the Bartabwa
ip may have functioned as a funnel for sediment crossing
e Kito Pass Fault Channel deposits in area Ia to the east
' the line of the Kito Pass Fault are more fossiliferous
86 specimens from 19 localities) than those in area Ib to
e west (59 specimens from 11 localities)

auna and faunal correlation

n extensive collection of fossils was made during the
72–73 field season It included 1,400 fragments of mam-
als, 500 fragments of fish, 3,000 mollusca and a variety
less common fauna and flora, from 132 fossiliferous
calities Many of the specimens have not yet been studied
detail but preliminary identifications are presented in the
unal list (Table 1) Figure 4 is a pictorial representation
the stratigraphic ranges of the various faunal and floral
:ments

A tentative correlation with the uppermost Vindobonian
s been attempted[3] on the basis of the fauna and particu-
·ly on the apparent absence of Hipparion The discovery
Hipparion in members D and E resolves much of the
:culation over the apparent absence of Equidae from sub-
haran Africa at this early date Hooijer[8] has concluded
it the Ngorora Equidae are the same species as the
rliest equids of northern Africa, and Eurasia

The Ngorora Formation is younger than the Fort Ternan
rmation from the evidence of radiometric dates and mam-
ilian faunas The Bovidae seem slightly more advanced
in their Fort Ternan counterparts (A Gentry, personal
mmunication) A Vindobonian age is clearly too old and
: Ngorora Formation is probably equivalent to the Val-
ian and Lower Turolian of Europe and possibly the
inji/Nagri Stages of the Siwalik Series

When additional dates have been established for tuff
rizons in the sediments it should be possible to estimate
ire precisely the age of these earliest sub-Saharan Equidae
present, whole rock $^{40}K/^{40}Ar$ age determinations suggest
:s of ~12 Myr for the underlying Tiim Phonolite and
; 5 Myr for the overlying Ewalel Phonolite[2,6] Sanidine
dspars from member B have yielded ages of ~11 94 and
2 31 Myr and ages of ~9 82 and ~9 68 Myr from
:mber D (J A Miller, personal communication)

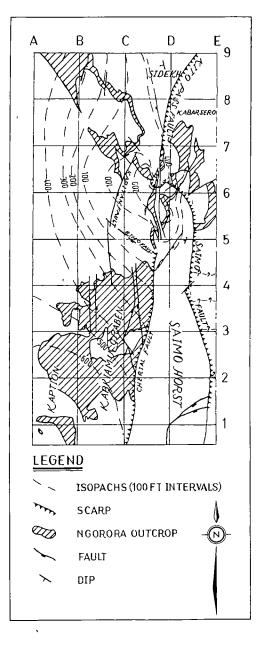
The oldest known remains of Hippopotamidae occur in
: Ngorora Formation[2] The number of specimens has
:n significantly increased by finds during the latest field
ison Other interesting elements of the fauna include a
minoid, a cercopithecoid, a new genus of large hyracoid,
new species of gomphothere[7], a canid, a mellivorine
istelid, a new species of Orycteropus, the ruminants
itragocerus, ?Pseudotragus, Palaeotragus, Gazella, ?Samo-
rium, and an antlered form, several rodents and a small
riodontine suid A hyaenid has also been recorded A
ge variety of molluscs has been collected, and impressions
several types of insect have been found, including ter-
tes, mosquitos, moths, and flies Of striking interest is the
:at difference between the rhinocerotid faunas of Ngorora[4]
d those of Fort Ternan This is strange in view of the
nilarity between the ruminants found at both localities
Several earlier determinations of taxa are incorrect
alicotheriidae[1] is now recognised as Hyracoidea


Fig 2   Thickness variation and major structural controls,
Ngorora Formation

Chilotherium[2] should be Chilotheridium[4] Tapir[3] should be
Listriodontinae, and Deinotherium hobleyi[2] should be Deino-
therium bozasi

Various plant fossils have been collected, including wood,
leaves and seed pods Among the Protista the diatom
Melosira sp is recorded, and calcareous algae are common
Among the Trachaeophytes, both Monocotyledons (palms
and grasses), and Dicotyledons (lianas, ?Celtis sp) and
several others are represented A bullrush-like plant was
found in member B No pollen has been found

The Ngorora fauna is not restricted to a single small
locality as is that at Fort Ternan, but occurs over a large
area It spans a period possibly as long as 3 Myr Its
value is enhanced by the detailed palaeogeomorphological
and palaeoenvironmental evidence that can be deduced for
the formation (Fig 4 and Table 2)

Palaeoenvironment

Reconstructions of palaeoenvironments often rely heavily on
fossils, and thus engender circular arguments about the
habitats occupied by different elements in the fauna Apart
from details of the topography of the basin floor already

*Previously unrecorded from the Ngorora Formation

discussed here, the Ngorora sediments yield evidence of a variety of conditions prevailing both during and after deposition Palaeoenvironmental indicators in the sediments include polygonal desiccation cracks, calcretes and other palaeosols, in situ plant remains, channelling and cross-bedding, bird footprints, evaporite deposits, rhythmic units, algal and oolitic limestones, subaerial tuffs, diatomites, chert nodules and other structures Table 2 summarises the evidence for the five members in three different areas

Member A predominantly comprises coarse, reworked pyroclastic material, with some primary elements (for instance around the Kaption volcanic centre) The coarse beds contain very few fossils, but the thin shaly horizon at the bottom of the type section contains rhizomes in position of growth At Chepchomus (C6, Fig 2), a few proboscidean and rhinocerotid remains were found, resting on the Tiim Phonolite At the top of member A some grit-filled channels occur, but these were poorly fossiliferous and yielded only a few reptilian fossils together with comminuted fish bones

During the deposition of member B, Kaption Volcano

◄Fig 3 Lithostratigraphic units and sedimentary characteristics, Ngorora Formation

was still intermittently active and was quite possibly a source of the accretionary lapilli tuff, one of the most reliable marker horizons in the Ngorora sequence In area 1b, there were several episodes of emergence of the land surface giving rise to palaeosols and weathering profiles In particular, there is a widespread pyrolusite nodule horizon in the Bartabwa area (C5, Fig 2) which seems to have been formed by subaerial weathering of the underlying tuffaceous bed It was subjected to contemporaneous channelling and winnowing, as evidenced by thinning of the unit and local concentration of the nodules into a conglomerate The accretionary lapilli tuff was deposited after the formation of the pyrolusite horizon, and soon acquired an active and flourishing plant growth, as shown by numerous rootlet casts In places, as at locality 2/1 (Kabarsero), it was channelled and potholed by running water A mile south of Bartabwa, casts of rhizomes occur in the accretionary lapilli tuff and at Kalimale (C6, Fig 2) plant growth and weathering were vigorous enough to destroy all the lapilli in a bed 45 cm thick, giving rise to an extensive calcrete (caliche) horizon Fortunately, patches of the original material have survived, thus allowing stratigraphic correlation

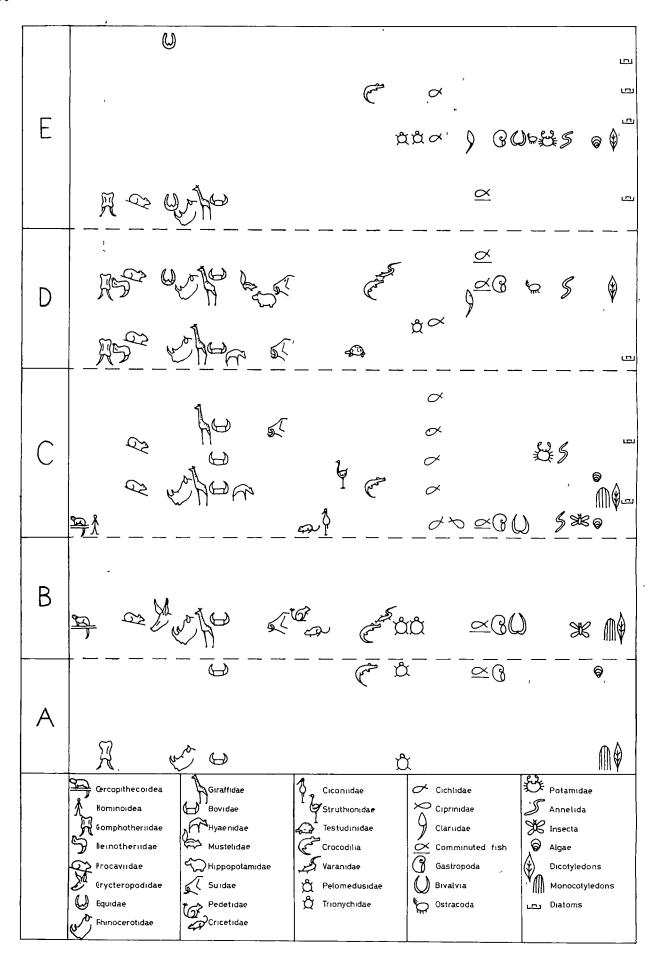
The varied fauna recorded from member B is of limited


Fig 4 Distribution of major faunal elements, Ngorora Formation

use in deducing the nature of the local palaeoenvironment, as nowhere is there a 'life assemblage'. It could have been derived from many miles away, and from several different environments. The ruminants, however, indicate an open or lightly wooded grassland habitat[5].

Kaption Volcano had ceased activity by the beginning of deposition of member C which was heralded by large scale faulting along both the Kito Pass–Saimo Fault system, and the Cherial–Kaption system. Three lakes were formed, one at Kabarsero (area I*a*), one in the Kapkiamu Graben (area II), and the third to the west of the Kaption Complex. The first was a fresh water lake, as shown by the diatoms and crabs, and could have been well oxygenated. Several regressions occurred and the sediments became suncracked and fissured, with the development of palaeosols. Some of the palaeosol horizons have yielded fossils, including articulated bones and, in one case, a complete skeleton. These occurrences are more likely to represent life assemblages than are those of members B and D. Taphonomic studies are being undertaken to determine the main differences between the two types of deposit. Potamid crabs indicate that the water of the Kabarsero lake was fresh. The Kapkiamu lake on the other hand was most probably an alkaline body of water; the shales were probably chemical precipitates (Judith Van Couvering, personal communication). A new form of stunted *Tilapia* is found in abundance in the shales, and is similar to *Tilapia grahami* found at the present day in the soda lake Magadi (Judith Van Couvering, personal communication). Beds of algal and oolitic limestone that give off a petroliferous odour when freshly broken also occur. They usually overlie suncracked horizons.

The shales and laminated clays were laid down in rhythmic fashion and possibly indicate seasonal fluctuations of climate. Both units are finely laminated, and record periodic increments of sediment. Fossil wood from member C contains well developed growth rings suggestive of fluctuating climatic conditions.

The juxtaposition of fresh and saline lakes comes as no surprise as there are two such systems in existence in the Kenya Rift Valley at the present time. Lakes Baringo and Hannington lie about 20 km apart and lakes Naivasha and Elmentaita lie about 25 km apart. The palaeolakes of Kabarsero and Kapkiamu were about 8 km apart. The area between them was one of low ground upon which a vigorous plant cover and palaeosols were developed. Contemporaneous erosion was occurring and in places channels are seen, but the relief was, in general, low. Some manganiferous weathering horizons were developed during this time, and it is above one of these, at locality 2/9 (C5, Fig. 2), that the hominoid molar was found. The third lake, west of Kaption, contained freshwater.

Member D began with rejuvenation which resulted in channelling, and the deposition of grits and conglomerates and coarse tuffaceous beds. There is a marked decrease in grain size to the west. Clay horizons are intercalated between the coarse units in a manner similar to those of member B. Unfortunately, landslip and scree obscure much of member D in area I*b*, but in area II there are several good exposures which contain suncracked horizons, palaeosols and other evidence of emergence or shallow water. Crabs, ostracods and fish are found at Kalimale (C6, Fig. 2) in a marginal lacustrine deposit, indicating freshwater conditions nearby.

Scree and landslip obscure much of member E in area I*b*, and in area II the unit has been eroded away almost completely. The lower part of the member is composed of well laminated, diatomaceous shales with numerous suncracked layers. The development of clastic dykes and 'sills' is in places spectacular. At Cheprimok (C5, Fig. 2) sedimentary rhythms are well developed with up to nine units comprised of a coarse volcaniclastic and fish-bearing lower part, followed by a shaly, suncracked portion. Zeolite formation is common and palaeosols are developed on some units. One

of these palaeosols contained the remains of a new gomphothere[7]. The lacustrine episode of member E was terminated by renewed movement along the faults which resulted in the lowering of area I*a* and the uplifting of areas I*b* and II which began to undergo erosion. In area I*a* sedimentation was continuous, but the energy of the environment had changed so that grits and conglomerates were deposited above the shales.

Table 2 Summary of palaeoenvironmental reconstructions, Ngorora Formation

Member	Area I*a*	Area I*b*	Area II
	Rejuvenation, giving rise to conglomerates and grits.	Uplifted by faulting with consequent erosion.	
E	Lacustrine, fresh water with numerous lake oscillations producing suncracks and clastic dykes.	Lacustrine, fresh water, well developed rhythmic units caused by lake oscillations. Some calcretes formed.	Record removed by erosion.
D	Fluviatile with several prolonged emergences marked by palaeosols. Ruminants suggest open or lightly wooded areas.	Marginal lacustrine and fluviatile; fresh water. Fluctuating lake levels with frequent desiccation.	Lacustrine environment with minor fluviatile episodes. Some palaeosols and desiccation cracks developed.
C	Freshwater lacustrine environment. Oscillating lake levels with prolonged emergences marked by palaeosols. Growth rings in wood suggest fluctuating climate.	Predominantly emergent with weathering and erosion. Minor paludal facies. Low relief.	Alkaline lacustrine conditions with very low energy. Many lake level fluctuations. Rhythmic units developed, with possible climatic control.
B	Fluviatile with some prolonged emergences and development of palaeosols. Possibly two primary tuffs. Vigorous plant growth.	Predominantly emergent with well developed palaeosols. Otherwise fluviatile. At least one primary tuff. Vigorous plant growth.	Little evidence, owing to proximity to volcanic centre. Thick primary tuffs.
A	Lacustrine at first followed by several lahars, primary agglomerates and tuffaceous sediments. Minor fluviatile facies.	Lahars, tuffaceous sediments; minor fluviatile facies.	Primary volcanic activity, near eruptive centre; tuffs, agglomerates and lavas.

The sedimentary sequence is overlain by lavas of the Ewalel Phonolite Formation which flowed north and covered much of the Ngorora Basin. Continued faulting along the Kito Pass and Saimo Faults, and later erosion led to re-exposure of the sediments. The area was then covered by the Kabarnet Trachyte Formation, K–Ar dated at about 7 Myr (ref. 2). Further faulting, in particular during the Pleistocene, resulted in the uplift of the Tugen Hills to their present height, and re-exposed the Ngorora Formation.

Chiefs of Baringo District for assistance in conducting the research and for permits to study and export the fossils. Mr Kiptalam Chepboi and Joshua Chetalam were of great assistance in the field. We acknowledge assistance from the staff of the Centre for Prehistory and Palaeontology, National Museums of Kenya, Nairobi and thank Mr and Mrs R. Leakey and Dr and Mrs P. Andrews for their hospitality.

Structure of tobacco mosaic virus at 6.7 Å resolution

K. C. Holmes, G. J. Stubbs, E. Mandelkow* & U. Gallwitz

Max-Planck Institut fur Medizinische Forschung Abteilung Biophysik, 69 Heidelberg, Jahnstr. 29, West Germany

The electron density distribution of tobacco mosaic virus has been determined to 6.7 Å resolution by analysis of the X-ray diffraction pattern given by oriented gels of the virus. This has been achieved by separation of overlapping Bessel function terms by a technique analogous to crystallographic isomorphous replacement. The course of the polypeptide chain of the coat protein may be traced for a large part of its length.

TOBACCO mosaic virus (TMV) consists of long, rod-like particles which can be made to form large regions of oriented gel in a capillary tube. These gels give a detailed diffraction pattern (Fig. 1), as was shown by Bernal and Fankuchen[1]. This demonstrates that TMV is periodic, repeating every 69 Å with a pseudo-repeat every 23 Å. The theoretical development by Cochran, Crick and Vand[2] of the diffraction pattern of a helix allowed Watson[3] to recognise that the diffraction pattern given by TMV gels was a typical helix diffraction pattern and moreover that the repeating unit of TMV must contain $3n + 1$ subunits in three turns. It was later shown by Franklin and Holmes[4] that there are 49 subunits in three turns. Franklin[5] and Caspar[6] independently used the method of isomorphous replacement applied to the zero layer line of TMV to calculate a radial density distribution of the virus, and Franklin[5] showed that the RNA is at a radius of 40 Å. Klug (unpublished) later confirmed that this is a single strand winding along the basic helix, by studies of the other layer lines.

Because the TMV particles are randomly oriented about their long axes, one obtains in a diffraction experiment the cylindrical average of the square of the Fourier transform of a single virus particle. Interparticle interference may be neglected, so the intensity is continuous. Franklin and Klug (unpublished) demonstrated that it should be possible to extend the method of isomorphous replacement as classically used in protein structure analysis to deal with the situation encountered in TMV. A number of theoretical and technical problems impeded the progress of this research and our paper represents the fruition of this attempt to determine the structure of TMV from oriented gels using the method of isomorphous replacement.

Major sources of difficulty

The amount of data available is limited and errors tend to be systematic, so that extremely accurate measurement and correction of data is required.

The main problem encountered concerns the location of heavy atoms. Because of the very high symmetry of TMV (49-fold) and the low resolution data available, Patterson methods were early shown to be impractical. Automatic search methods based on R-factor minimisation using single heavy atom derivatives gave ambiguous results. The use of double heavy atom derivatives together with the single heavy atom

derivatives can partially remove these ambiguities[7] but a full scale R-factor search using five heavy atom derivatives and two double derivatives, and more accurate data was required in this work to yield unambiguous heavy atom positions. These methods are described briefly below.

The problem of cylindrical averaging is solved in two stages. At low resolution (10–15 Å) the diffraction intensities are unaltered by the averaging, because of the high symmetry of the TMV particle. Therefore it is possible to reconstruct the electron density of virus by establishing the phases of the observed intensities by the normal method of isomorphous replacement. At higher resolution new methods have been required, based on an extension of the isomorphous replacement method.

Data collection

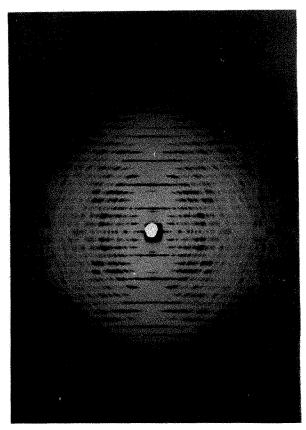
Data were collected with a double-focused monochromatised beam (see Fig. 1) and a computer-controlled densitometer. The major corrections were background subtraction and a correction


Fig. 1 A fibre diffraction pattern from an oriented gel of TMV. The exposure time was 87 h in an evacuated Guinier focusing camera (specimen film distance 11.2 cm) using a point focused beam from two bent quartz focusing monochromators and an Elliott fine focus rotating anode tube.

Table 1 Symbols used in this paper

R, Reciprocal space radius
l, Layer line index
c, Axial repeat (69 Å in TMV)
r, Real space radius
φ, Real space azimuthal angle (cylindrical coordinates)
z, Real space vertical coordinate
f, Atomic scattering factor
F, Structure factor
J_n, Bessel function, order n

for disorientation. Automatic background subtraction had not been successful, because arcs from strong spots extend into the region between layer lines where background is measured. But an interactive computer display system using manual intervention where necessary to override automatic procedures has proved adequate. These and other developments are described by Barrington Leigh[8] and Mandelkow[9]. The correction for disorientation has been described by Holmes and Barrington Leigh[10] and Stubbs[11].

Location of heavy atoms

A summary of previous attempts to locate the heavy atoms is given in ref. 7. The use of single site substitutions was of paramount importance in the initial location. The heavy atoms were located in three stages:

Determination of r and f. Radius and occupancy are the only parameters which affect the intensity on the inner centric part of the zero layer line. They may be determined by comparing the difference between the native and derivative structure factors (G) with the expected structure factor of a heavy atom ($fJ_0(2\pi Rr)$). The parameters are refined by a least squares procedure. An exact description of the process is given by Mandelkow and Holmes[15].

Determination of φ and z. It can be seen from equation (2) that, for a given Bessel function term, the phase Φ of the contribution of one atom to G is a constant

$$\Phi = -n\varphi_j + 2\pi l z_j/c$$

where r_j, φ_j, z_j are the cylindrical polar coordinates of the heavy atom. Φ may be found by a search procedure[8], in which the least-squares R-factor for each layer line

$$R = \sum (|F_H|_{obs} - |F_H|_{calc})^2$$

is minimised with respect to Φ. The values of Φ found from different layer lines can be combined to find φ_j and z_j. The procedure is limited to the regions of the diffraction pattern where Gs do not overlap.

Refinement. Refinement analogous to conventional crystallographic heavy-atom refinement[16] was carried out on the heavy atom r, φ and z coordinates by an extension of the process outlined above. There were insufficient data to refine occupancy or temperature factor.

Cylindrical averaging

The structure factor of a helix of repeating subunits was first evaluated by Cochran, Crick and Vand[2]. From their results, Waser[12] and Franklin and Klug[13] calculated the cylindrically averaged intensity. In the notation of Klug, Crick and Wyckoff[14] this is

$$I = \sum_n G_{nl} G^*_{nl} \tag{1}$$

where

$$G_{nl} = \sum_j f_j J_n(2\pi R r_j) \exp i(-n\varphi_j + 2\pi l z_j/c). \tag{2}$$

The summation in equation (2) is over all the atoms in the asymmetric unit. The notation is given in Table 1.

The summation over n in equation (1) is confined to those values of n which obey the helix selection rule

$$l = tn + um$$

where the helix has u subunits in t turns (49 and 3 for TMV); m is any integer. Since a Bessel function has a very low value until the argument is nearly equal to the order only a small number of different orders (and thus G terms) can contribute to the intensity at low resolution. For TMV to a resolution of about 12 Å, there is only one term, and two terms suffice for a resolution of 6–7 Å.

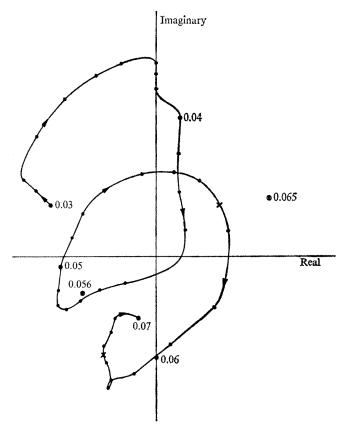
To perform a Fourier inversion and thus obtain an electron density map, the real and imaginary parts of each G must be known. The problem may be formulated in a way analogous to the classic crystallographic phase problem but with three unknown parameters rather than one. These may be considered as the phase of each of two terms originating from different


Fig. 2 Continuity of the transform of TMV, for layer line 1, $R = 0.030$ to 0.070. Each dot represents the value of the most probable G on the Argand diagram. The line connects dots adjacent in R. Circled dots do not fit the general continuity. The crosses represent minor peaks in the probability distribution of such discontinuous points, which do fit the continuity. The points represented by crosses are therefore accepted as the value of G to be used, rather than the circled dots. Argand diagrams such as this have previously been used by A. Klug (personal communication).

order Bessel functions (see equations (1) and (2)) and the ratio of their amplitudes, which for convenience is often expressed as the tangent of a third angle. The problem is equivalent to searching over the surface of a four-dimensional hypersphere using four or more heavy atom derivatives to determine the correct hyperspherical (three component) phase angle. In practice, however, it is more convenient to determine the G parts directly. They can be found by the method of isomorphous replacement. If a heavy atom is bound to the structure, and its position is known (see below), its contribution to G can be

Table 2 Heavy atom derivatives

Ligand	Strain	Residue	f	$r(\text{Å})$	$\varphi(°)$	$z(\text{Å})$
DMA	*Ni*-2068	139	40	72	0	0
MMN	*Vulgare*	27	32	56.7	16.0	11.7
OsO₄	*Vulgare*	1?	35	92.5	5.7	9.4
SHIMS-MMN	*Vulgare*	68(+27)	25	71.1	5.3	−1.3
Pb²⁺	*Vulgare*	115/116	24	25.4	7.1	20.6
Double derivatives (excluding SHIMS)						
DMA/Os	*Ni*-2068	139/1?				
MMN	*Ni*-2068	139/27				

SHIMS, sulphydryl imidoester[27]; DMA, dimercury acetic acid; MMN, methylmercury nitrate[4]. Units of f are arbitrary, and correspond to approximately one-third of an electron.

calculated. If this is $a+ib$, and $G = A+iB$, we have from equation (1)

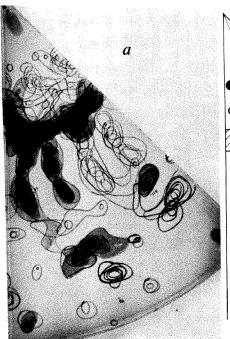
$$I_H = \sum (A+a)^2 + (B+b)^2 \qquad (3)$$

To solve unambiguously for all As and Bs, as many heavy atom derivatives are required as there terms in the summation in equation (3). The solution may then be found numerically, by a procedure quite analogous to conventional phase determination. This requires a great deal of computing, however, so an analytical procedure has been developed (Diamond and Stubbs, unpublished, based on the usual assumption that there are no errors in native intensities. With this assumption a series of equations of the type (3) may be reduced to linear equations, errors in which are minimised subject to the non-linear constraint implied by equation (1). The results will usually take the form of the peaks of a probability distribution for the pairs (A, B). It would be quite possible to accept the most probable set of As and Bs, treating each measured point on the fibre diagram separately. But to do so would be to neglect an important constraint on G.

The continuity constraint

As mentioned above (equation (2)), G is a continuous function of R, and the restriction $r_{max} < 90$ Å (the maximum radius of the particle) puts a limit on the rate of fluctuation in G. If, for example, a series of points along a layer line have smoothly varying values of A and B, except for one point, a smaller peak in the probability distribution of the discontinuous point often corresponds to the value of the smooth curve. This is illustrated in Fig. 2 for the single Bessel function case. The more compli-

cated situations which arise when two Bessel functions are present can be dealt with either in the same way (by inspection), or by a semi-quantitative procedure suitable for a computer (Stubbs, unpublished). Thus, real and imaginary parts for each G can be determined which provide an optimum balance between probabilities based on isomorphous replacement data and the constraint of continuity.

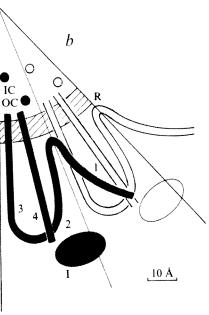
The derivatives


Four single-site derivatives and three double derivatives, with a total of five independent sites were used. The double derivatives were originally used to assist in the location of heavy atom sites. In this work, their main function was to reduce errors by providing partially independent extra data, but in the last few rounds of refinement, the methylmercury nitrate site at residue 139 (see Table 2) was freed from the dimercury acetate site. The movement was in fact very small.

Table 2 summarises the information on the derivatives. Because of the importance of single sites, sulphydryl-mercury reactions were used whenever possible. The *Ni*-2068 mutation[17] was used because it contains only one sequence change, Tyr 139 → Cys. The large dimercury acetic acid (DMA) group can react with this residue, but not with Cys 27, which only reacts with small mercurials.

The osmium site is tentatively assigned to the N-terminus, because it is the same as the N-terminus of the strain U2 of TMV[15]. This strain differs from *vulgare* in 35 amino acids of the coat protein, but gives a very similar diffraction pattern. The assignment is made plausible by the fact that a difference Fourier between TMV-*vulgare* and U2 shows no significant differences at radii greater than 70 Å. The chemical location of the lead site is uncertain. Butler and Durham[18] concluded that the reaction, which is believed to be with carboxyl groups (see ref. 19), could only be with Asp 115 and Asp 116.

The electron density map

Apart from a short section of layer line 3 where there are three G terms (and this section has relatively low intensity so that it could be omitted), only one or two G terms contribute to the data to a resolution of 6.7 Å and we were able to evaluate the A and B parts of each G term within this region. This was done


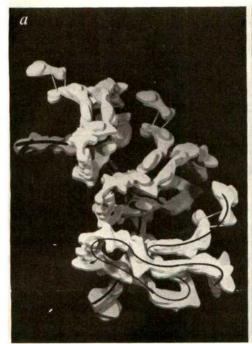


Fig. 3 *a*, Five sections of the electron density map, at 2 Å intervals in *z*. The sections contain two molecules adjacent in φ. One molecule and the RNA strand are shaded. Clearly visible are the RNA, parts of ribbons 2 and 3 (see Fig. 4*b*) and the C-terminus region. *b*, Schematic diagram of the main features in the electron density map. The diagram represents two subunits, one being shown by open symbols for convenience. IC, Inner column; OC, outer column; I, island; R, RNA; 1, 2, 3, 4, ribbons.
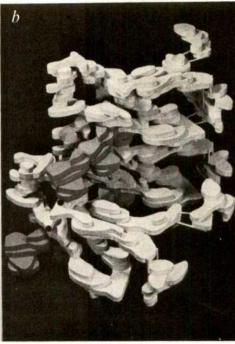

Fig. 4 Balsa wood models of the electron density. *a*, A half circle of RNA is shown (heavy line) with three protein molecules arranged along the TMV helix. Every other subunit has been omitted for clarity. The main chain of the protein is shown (light line). *b*, Three subunits of TMV protein, showing the interaction between subunits in successive turns of the helix. Note the three points of RNA-protein interaction, which are marked (●).

by trapezoidal integration at intervals of 0.001 Å^{-1} along each layer line. Compared with the mean wavelength of the *G*s 0.001 Å^{-1} is a fine interval. A Fourier inversion was computed. Five sections of the resultant electron density map are shown in Fig. 3*a*. Figure 3*b* is a summary of the main concentrations of electron density. The very strong helical ribbon at about 40 Å radius may be identified as RNA. The rest of the density, which must be coat protein, can be roughly divided into four approximately radial ribbons between 40 and 70 Å radius, two columns of density at 22 and 32 Å and an island of density between 75 and 85 Å. We can use the chemical information available about the protein to trace some of the chain.

Three of the ribbons form one continuous chain of density touching the RNA at two points. Residues 27 and 68 are labelled by heavy atoms, and appear to be in this chain. Since we believe the N-terminus to be at a radius of about 90 Å (see Table 2), we continue the chain back from residue 27 into the island, crossing at the only point which avoids very low densities.

Residue 139 is labelled, and is close to the inner edge of the island, so it seems that the C-terminus is also at high radius. This is confirmed by its availability to carboxypeptidase[20]. Therefore, the fourth ribbon must take the sequence from the RNA interface back to the island, and all the density inside the RNA helix must connect the third and fourth ribbons. This would agree with Butler and Durham's[18] location of the lead on residues 115 and 116.

The inner density is difficult to follow, but a tentative interpretation can be made. It seems that the chain probably runs up the inner column and down the outer, before crossing the RNA to join the fourth ribbon.

An interesting feature of this interpretation is that the island contains the C-terminus of one subunit and the N-terminus of the adjacent subunit. We would emphasise that this feature of the interpretation is somewhat preliminary.

Figure 4 consists of two photographs of balsa wood models of three subunits of TMV protein and strands of RNA. It is clear that the structure is essentially four fairly straight chains, with the RNA in a hollow on top of the molecule.

Conclusions from the map

Even though the map is only at 6.7 Å resolution, the following conclusions may be drawn:

First, the map suggests there is little β sheet since this would show up as non-resolved regions of high density at this resolution. Apart from very short sequences, the only place where a β sheet could be accommodated would be the island, which contains at most 20% of the protein.

Second, there are several regions of high protein density which would be consistent with α-helix, including two regions of high, rod-like density which are very good candidates for helices. These are probably in the vicinity of residues 55 and 95. α-helix was predicted at the first of these residues by Schiffer and Edmundson[21] and by Leberman[22], and Leberman also predicted the second. In fact, all of Leberman's five α-helical regions and five of Schiffer and Edmundson's six regions could be in or near our regions of high density.

Another interesting feature is the points of contact with the RNA. There are three, all in regions which are conserved in many strains and viable mutants of TMV. Furthermore, all three contain invariant arginines (residues 41, 90 and 92, 113) which have often been suggested as possible residues for interacting with phosphate groups.

Finally, the island of density is interesting. It seems to be joined to the rest of the protein by a region of low density which may be a hinge allowing some freedom of movement in the *z*-direction. Caspar and Holmes[23] concluded from studies of the *Dahlemense* strain that the outermost part of the subunit in *Dahlemense* TMV is periodically perturbed. It is possible that the structure involved in the *Dahlemense* perturbation is the outer island and its associated hinge.

This work is continuing, although the maximum resolution obtainable from this approach is probably only 5 Å. Klug and his coworkers in Cambridge are working on the crystal structure of the two-layer 17-fold disks of the coat protein[24-26] and it should be possible to take this work to atomic resolution. Eventually we hope to combine the two maps to obtain an atomic model of the entire virus.

Control of somite number during morphogenesis of a vertebrate, *Xenopus laevis*

Jonathan Cooke

Division of Developmental Biology, National Institute for Medical Research, Mill Hill, London NW7 1AA, UK

During Xenopus *embryogenesis and early growth, somite number stays close to a species-typical value for each morphological stage. This remains true even after operations on blastulae which lead to the development of abnormally small but otherwise complete early embryos, involving reduction in number of cells assigned to each somite. Evidence presented suggests that a body-position gradient may be involved, but in rather different ways at different stages, in controlling total somite number.*

SPATIAL patterns of cell differentiation underlying morphogenesis in early embryos fall into two categories. One is the specification of non-repeating anatomical features such as heart, kidney, and limb and tail rudiments, henceforth referred to as the 'whole-body pattern'. The other is the specification of serially repeating units of morphogenesis, typified in vertebrate embryos by the somites, the segmental blocks of mesoderm from which serially repeated elements of axial skeleton and musculature develop. Development of whole-body and repeated patterns is coordinated in space, in that somite no. *n* in a particular species is quite reliably opposite, for instance, the hindlimb bud.

An elaboration of earlier gradient models, proposed by Wolpert[1], postulates a continuously graded cellular 'positional information' variable across tissue. Commitment of a cell to a given developmental pathway depends on its 'interpretation' of the value of the variable at a given point in the gradient. On such a model, although the spatial variable underlying pattern formation is simply distributed, the burden on the genetic machinery underlying cellular interpretation is correspondingly demanding, and the mechanism becomes implausible for serially repeated structures. This is because it is hard to see how the interpretative system within cells could be so organised as to react in a particular way, for example by deadhesion to form fissures between the successive, similar somite blocks, only to some thirty, regularly dispersed values on a gradient, although ignoring or reacting differently to intervening ones.

Models that postulate prepatterns[2-5] in developing tissue have therefore been preferred. These are defined as the regular repetition in space of some special situation (for example a concentration peak of a 'morphogen' substance), each repetition causing development of one of the pattern elements subsequently seen in differentiation. The problem of interpretation by cells then becomes simplified, perhaps even to a binary choice controlled by a threshold concentration (for example, deadhesion as opposed to adhesion for somites, bristle-cell as opposed to epidermis for certain insect patterns). There are, however, other difficulties, connected with repeatability and consistency of the patterns in

space. In the case of somites, the observed constancy and regularity of element size and number[6] is embarrassing for all known prepattern models[7,8].

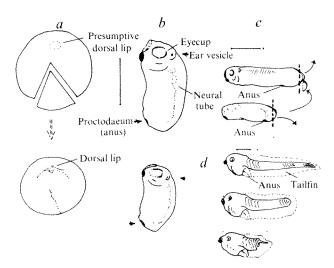
Regulation is an even more profound problem. When overall cell number of early vertebrate embryos is reduced, cell numbers developing along each pathway are reduced to give a normally proportioned whole-body pattern. There are several plausible mechanisms for regulating the steepness of a continuous gradient to account for such regulations[1]. The distance between 'peaks' in prepatterns underlying repeated structure, on current models[3,4], is determined, however, by physiochemical parameters (diffusion and allosteric interaction constants for specific molecules) which cannot easily be imagined as modifiable by changing the overall dimensions of the tissue. A prediction is therefore that the number of elements in a repeating pattern will be reduced from normal in direct proportion to amount of early embryonic tissue removed, if the latter amount corresponds to more than one whole unit's worth.


Fig. 1 *a*, Vegetal view of stage 8 blastula showing size reduction operation. This was performed in two-thirds strength Niu–Twitty solution[13], but with the $Ca^{2+}Mg^{2+}$ (Cl⁻) concentration doubled and *p*H brought to 7.0 with HCl. Healing was for 1 h in a fitting depression in wax, before storage to develop in one-tenth strength solution. Healed small early gastrula shown. In control siblings only one of the two cuts used to remove material was made, and healing allowed in the same solution. Normal repositioning of an excised section could not be achieved, and development of such animals was too disturbed for use as control material. *b*, Neurulae at stage 25, control and experimental, showing a size difference close to the maximum compatible with final development of experimental to the later larval stages. *c*, Early 40s stage larvae, control, and after tailbud tips removal at stage 24 and stage 26. Scale line represents approximately 1 mm throughout.
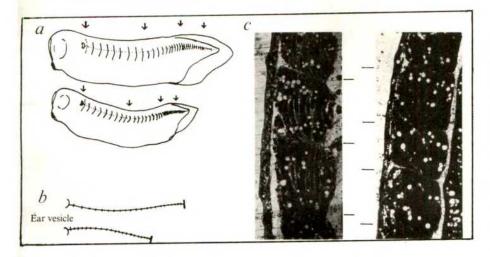

Fig. 2 *a, Camera lucida* drawing of an experimental and control pair at stage 34/35, each having 35 or 36 postotic somites, as seen after epidermis removal during fixation. Postotic axial length ratio now 0.83, having been 0.70 in stage 23 tailbud embryos. Arrows mark ear vesicle, 10th, 20th and 30th somites, seen to be appropriately placed. Somite boundaries are marked, but their outlines not drawn. *b, Camera lucida* record of somite boundaries in isolated axes between ear vesicle and level of proctodaeum. Length ratio best estimate is 0.75. Experimental has 21–22 somites, whilst its control has 23. *c,* Horizontal 1-μm epon sections stained with toluidine blue, showing mid-trunk somites of an experimental and its control at stage 25/26. The shortness of the experimental somites can be seen. Marker lines are opposite inter-somite boundaries.

Regulations of somite number

Measurements of total length and of total somite number, in synchronously developing sibling *Xenopus* larvae, show no detectable correlation between the two. This suggests that despite variation in amount of egg material, total length variation in the somite-forming tissue is not an important source of variation in somite number. I have tested this conclusion further by removing animal-vegetal sectors from near the ventral meridian of stage 8 (ref. 9) blastulae (Fig. 1a and b) following which tailbud stage embryos are obtained of as little as five-eighths normal length. These animals have developed a complete whole-body pattern across their reduced number of cells. Cell counts per area in epidermal preparations show no evidence that extra mitoses have occurred by these stages in the experimental animals; they have regulated in the classic sense that the positional information theory[1] was evolved to explain.

I have counted and measured the numbers and sizes of post-ear-vesicle somites in operated embryos and their control siblings, fixed at the same time post fertilisation. Embryos down to little over two-thirds control length show essentially normal numbers and relative positions of somites at each stage (Fig. 2 and Table 1), revealing that the available prepattern models cannot account for somite formation.

Another class of mechanisms which can be clearly ruled out are those that would depend on particular, species-specific cell numbers. The length of individual somites seems to be determined by total length of tissue available, and numbers of cells per somite adjusted accordingly. Both within and between control embryos, cell numbers in the original lengths of somites are almost constant throughout the trunk region, but in haploid embryos, having more, smaller cells than normal, cell number per somite is correspondingly larger[6]. This is easy to check because true mitosis in *Xenopus* somites is very rare after the process of deadhesion and rotation of successive blocks of somite cells[6]. Cell numbers across somite widths in later embryos are thus records of the numbers between fissures at the time of somite formation. In my experiments, the smaller somites in fact contain fewer cells than normal in this dimension, which is the one determining how many somites are 'fitted in' to the whole-body pattern.

Still smaller embryos tend not to develop beyond mid-tailbud stages, and to have poorly defined somites that cannot be counted. This may be for mechanical reasons such as reduced stretching of the normal-sized cells, so that they are insufficiently spindle-shaped to perform rotation movements, but other explanations to do with the as yet obscure process of pattern formation itself are possible. One exceptional embryo, measuring only 0.6 of control length between ear vesicle and rear end, showed 4 clear rotated somites on

Table 1 Comparison of numbers and lengths of somites formed behind ear vesicle level, relative to length of axis traversed by the somite morphogenetic process, in experimental small embryos and synchronous control siblings

Note: "Somite morphogenesis extends to tailbud" appears at the left between Set IV and Set V rows.

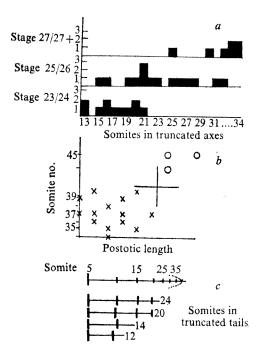
Embryos were either prepared for wax or epon sectioning, or stripped immediately of epidermis for somite counting and measurement. Measurements were derived from constant scale *camera lucida* drawing, and cells in widths of mid-trunk somites were counted at notochord level in horizontal section[6]. Nuclear counts in epidermal whole mounts and sections give no evidence of smaller cells, as a result of compensatory mitosis since operations, by early tailbud stages. Sets consist each of experimental and synchronous control embryos, fixed at the same time after fertilisation.


Fig. 3 *a*, Histogram of somite numbers in truncated axes of a population of siblings at stage 39, following tailbud tip removal at stages 23/24, 25/26 and 27/27+, respectively. Line represents average postotic somite number in synchronous control (unoperated) population. *b*, Scale chart of mean *camera lucida* positions of boundaries between successive groups of 5 postotic somites in the control population of *a*, in comparison with records, drawn in alignment, for four individual truncated axes.

one side, anteriorly, each 5–6 rather than the normal 9–10 cells in width (original length).

Yet another alternative model, in which appropriately proportioned blocks of cells are cut off by a local adaptation of the lengths of blocks to the width and depth of the column of presomite cells (the latter dimension regulating as part of the whole-body pattern after operations), can be ruled out. In the related amphibian *Bombina*, the morphogenesis of which is slower, I have been able to remove, at the close of gastrulation, a longitudinal strip of the sheet of cells that will later form the somite column in the trunk region, on one side only. Such animals develop with the column of presomite cells much shallower and narrower on the operated than on the normal side, over a distance equivalent to many somites. Somite numbers formed, however, prove to be equal on each side, in register, and normal for the species.

Somite number and growth controlled together during tail development

During mid-tailbud stages in amphibian embryos, when the above observations were made, the first true cellular growth, as opposed to cleavage, occurs especially in the tailbud region. Somite segmentation extends progressively into this, posteriorly, with rapid growth occurring at all levels not yet reached by onset of notochord and somite histogenesis. But increasing somite number remains in register with morphogenesis throughout growth in both control and experimental (initially small) animals, so segmentation must continuously be adapted to total length of tissue available.

The problem of coordination of growth and differentiation arises most acutely for structures such as limb and tail rudiments, in which the two processes are proceeding simultaneously. Summerbell *et al.*[10] have suggested that in the developing chick limb, positional value of mesoderm cells, though they are dividing throughout the organ in true growth, changes with time only in a terminal un-

differentiated 'progress zone', where progressively more 'distal' values are achieved. Thus following successively later apical ectodermal ridge removals from wingbuds, a succession of more nearly complete, yet still distally truncated patterns were finally differentiated.

I have performed analogous experiments on *Xenopus* early tailbuds, and the results suggest that pattern formation is controlled in a similar manner. Following a suggestion of Graeme Mitchison, a terminal piece of undifferentiated tailtip mesoderm with ectoderm, always some 300 μm long, has been removed from sibling embryos at a continuous range of tailbud stages, followed by counting of the total somites formed in the truncated tails of the advanced larvae 48 h later. Figure 3 shows typical results, from one of several such experiments consisting of 33 tailtip removals and 14 controls. Following tip removals between stages 23 and 27, that is, well before somite formation has reached the undifferentiated tip issue, the tails of the advanced larvae are sharply truncated, ending in short cone- or rod-shaped blastemas. They contain appropriate numbers of normal sized somites up to the levels of truncation (as measured by length), and the tailfin morphology, cumulative tail growth and lengths of successive groups of five somites are all literally parallel with controls up to the truncation point (see Figs 1c and 3c). The correlation between the proportion of a whole axis remaining, as judged by these criteria, and age of tip removal (Fig. 3a) is highly significant in spite of inevitable variation in the amount of tissue removed, particularly from very squat early tailbuds.

From Fig. 3a it seems likely that the somite numbers actually seen in truncated tails are a random sample from all possible integer numbers up to that in controls. When all the experimental populations are considered, no gaps in the series or traces of any stepwise distribution are seen. Taken together, these results indicate that position value of cells is fixed, as a continuous variable[5] of some nature rather than in prepattern terms, very early during tailbud growth, and probably when individual cells are near the tip. Thereafter, it would be maintained with at most a local 'averaging' between neighbour (daughter?) cells.

Alternatively, the position values for an entire tail (that is for all the somite complement) could be present across the cells of a very young, squat tailbud, and thereafter maintained by clonal inheritance and averaging throughout growth. Then, removal of a uniform amount of tailtip from progressively older tailbuds would result in truncation of progressively less of the distal portion of a position gradient, and hence of somite pattern. This concept would however imply one of two novel features: either an initial gradient, at a time of setting up, that is much steeper posteriorly than in the trunk (implied by the large number of presumptive somite positions there in relatively little tissue) or else a changing relationship, posteriorly, between 'wavelength' of the somite forming process and gradient steepness. The former is possibly not readily allowed for by any of the models for maintaining gradients[1], but the second idea cannot be discounted at present. Indeed, the number of cells in the width (that is the length, on first formation) of somites does decrease in a regular way posteriorly (my unpublished data).

Idea of a locally inherited position value gradient

Amphibian mesodermal cells are probably undetermined with respect to whole-body position value (however this is encoded) only in two situations: while within the regulating positional information gradient that embraces trunk values and exists across the early embryo until around gastrulation (see the miniature whole embryo discussed earlier), or else while in a 'progress zone' of labile region near the tailbud tip, where the graded series of values is extended to complete the axis. Such a position gradient, if preserved by

local mechanisms among descendants of cells, would still be available to cause coordinated placement of later-developing structures (for example: limbbuds, or the special behaviours of particular spinal nerves in the series[11]).

The results discussed indicate that the steepness, or rate of change within embryonic tissue, of the positional variable is able to control the distance between repetitions of a certain cellular event in the animal's long axis. For reasons given at the outset, it is hard to imagine that this could be by direct interpretations of positional values as has been postulated for the whole-body pattern, but a theory of somite control, accounting for the known features of the process and its coordination with other morphogenesis, is to be presented elsewhere[12].

Positional signalling and specification of digits in chick limb morphogenesis

C. Tickle, D. Summerbell & L. Wolpert

Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School, London W1P 6DB, UK

The interpretation of positional information can provide the basis for pattern formation in limb morphogenesis. The gradient in positional information along the antero–posterior axis, which is specified with respect to a localised boundary region, can be modified by grafting this region to successive positions along the axis. The pattern of digits obtained is consistent with a model based on diffusion of a labile morphogen and is thus similar to models proposed for the development of pattern in invertebrates.

RECENT approaches to pattern formation, that is the development of the spatial pattern of cellular differentiation, have made use of the concept of positional information[1]. The suggestion is that cells are assigned positional information in relation to a coordinate system and the interpretation of this leads to appropriate cytodifferentiation. This is essentially an extension of earlier gradient models[2]. Good evidence for positional information comes mainly from studies on the insect epidermis[3,4], insect eggs[5] and regeneration in hydra[6,7] but there are few demonstrated instances in vertebrates. We have suggested that the development of the pattern of the cartilaginous elements of the chick wing can be viewed in terms of the concept of positional information[8,9]. The positional values assigned to the cells define a set of cell states, some of which will, for example, result in cartilage formation and others in the formation of muscle. We have proposed that the cells are assigned positional values along two of the axes, the proximo–distal and antero–posterior, by somewhat different mechanisms, the two positional values providing a two-dimensional coordinate system (Fig. 1). For the proximal–distal axis we have presented evidence that there is autonomous change of positional value with time in the progress zone[8,10]. This is a region about 300 μm thick at the distal end which is specified by the apical ectodermal ridge (AER). Since all the cells in the progress zone are dividing, cells constantly leave the zone, those coming out later being assigned more distal positional values. This mechanism does not require signalling between the mesenchymal cells, although there may well be short range interactions, or local interactions involving averaging

of positional value. By contrast, for the antero–posterior axis, we suggested that the positional value is specified by a positional signal from the polarising region at the posterior edge of the progress zone[9,11]. This was a conjecture based upon the work of Saunders[12,13] and we now present evidence for a signal from the polarising region providing positional information for the specification of the digits in the chick wing. Crick[14] has emphasised that diffusion could provide the basis for positional information and our data is consistent with such a mechanism.

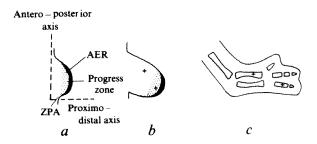
The zone of polarising activity (ZPA) was discovered by Saunders and Gasseling[12]. An additional ZPA grafted to a more anterior level in contact with the AER, resulted in the formation of extra skeletal elements. Of particular interest was the relationship of the additional elements with the normal ones; when between the host ZPA and the grafted ZPA, they were always in mirror image symmetry about the long axis. Moreover the polarity—the order of the induced digits—was such that there was a strong


Fig. 1 The chick wing bud starts as a small bulge (*a*) and grows out as a tongue-shaped mass consisting of mesenchyme encased in ectoderm. The ectoderm has a thickening running along the distal rim, the apical ectodermal ridge (AER). The skeletal and muscular elements differentiate within the mesenchyme in a proximo–distal sequence (*c*). It is suggested that cells are assigned positional information when they are in the progress zone, along, for example, the antero–posterior and the proximo–distal axes. In the case of the antero–posterior axis, position is specified with respect to distance from the zone of polarising activity (ZPA). In *b* there are two points marked (+), the one outside the progress zone has already had its positional information specified, while the other is in the process of being specified. At a later stage, cells at these points interpret the positional information giving rise to tissues of the radius and digit 4 respectively (*c*).

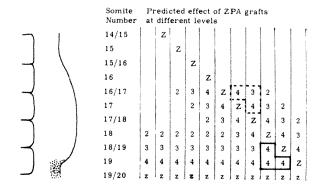
19/20	z z z z z z z z z z z


Fig. 2 At the left is the outline of the normal limb bud and the somites at stage 19: the normal position of the ZPA (z) is also shown stippled. The predicted pattern of digits when an additional ZPA (z) is grafted to successive positions along the antero–posterior axis is shown in the columns on the right. It is based on the assumption that the digits are specified with respect to their distance to the nearest ZPA, that is a simple linear gradient. The predictions are only meant to show in diagrammatic form the overall pattern, and changes in limb geometry have not been allowed for. Nevertheless all the cases have been found experimentally except those enclosed by the solid line where either no digits were formed, or were much reduced. Those cases in which the digits are enclosed by a dashed line, are where digits formed but were sometimes inconsistent with the prediction, that is instead of 43, either 432 or 32 was obtained.

tendency for posterior structures to be adjacent to the graft[13]. We have interpreted these results as implying that the ZPA is the boundary or reference region for the antero–posterior axis of positional information[9,11]. Since only cells in the progress zone can respond to the influence of the ZPA[15] the character of the digits may be specified by their distance from the ZPA at the time when they are leaving the progress zone. One way in which a gradient in positional value could be set up would be by the ZPA being the source of a diffusible morphogen which would act as a positional signal.

In the first instance we will consider a model which is not dependent on any specific assumptions with respect to mechanism, such as diffusion, and only assumes that positional information is specified by the distance from the

Table 1 Formation of digits between the grafted ZPA and the host ZPA when the ZPA is placed in successive positions along the antero–posterior axis

* In some of these cases the identification of the anterior digit 4 was equivocal.

nearest ZPA; that is we assume a simple linear gradient. The best markers along the antero–posterior axis are the three digits (II), (III) and (IV) (which for convenience we will represent as 2, 3, 4) since they can usually be recognised unequivocally by the number of elements and distinct morphological characteristics. We will thus confine our attention to them and assume that the nature of the digit specified is determined by its distance from the nearest ZPA. We have shown diagrammatically the predicted pattern of digits when an additional ZPA is placed in successive positions along the antero–posterior axis, the host's ZPA being left intact (Fig. 2). From this several interesting features emerge. First, digit 2 will form wherever the gradient has an appropriately low level and thus it should be possible to obtain an additional digit 2 on its own when the ZPA is placed in a sufficiently anterior position. Second, one does not get discontinuities such as digit 2 next to digit 4. Third, there is no requirement for intrinsic polarity, that is the signal from the ZPA propagates in both directions.

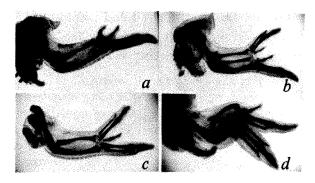
In the normal limb the digits form mainly in the posterior half of the limb, that is from the region between somites


Fig. 3 A series of dorsal views of whole mounts of right limbs with grafts showing the pattern of digits formed as the grafted ZPA is placed in successively posterior positions. The digits formed are as follows from anterior to posterior; *a*, 2234; *b*, 432234; *c*, 43234 and *d*, 234434.

18 and 19[16]. The ZPA occupies a position immediately posterior to this (Fig. 2). The anterior half of the limb does not seem to participate in formation of distal structures and this may be related to the asymmetry of the AER which is better developed posteriorly.

Grafting the ZPA

We have substantially confirmed all the predictions by grafting ZPA tissue to successive positions along the antero–posterior axis. ZPAs were taken from stages 18 to 21 and pinned with a small piece of platinum wire into a hole cut into the edge of the limb[15]. The graft was thus always in contact with the AER except when placed in more anterior positions. We have made use of the somites as markers for position along the antero–posterior axis. Since the distance between somite centres is about 250 μm and the size of the ZPA graft is about the same, the error in the positioning of the graft is about half the width of a somite. The results are substantially the same for stage 18 and 20 hosts (Table 1).

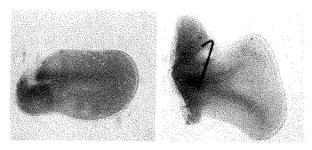
Considering structures posterior to the graft first, it can be seen that when the graft was opposite somite 15 which appears to be just outside the anterior border of the limb bud, normal limbs developed in most cases. This confirms that the ZPA from the wing does not itself differentiate into any recognisable structure[15]. This suggests that the signal from the ZPA is rather short range and that body wall tissue is not competent to respond to the signal. Of particular importance is the development of hands comprising 2234 (Fig. 3a) and 32234 when the graft is in the


Fig. 4 Dorsal view of whole mounts of the normal and grafted right limbs at stage 24. The ZPA was placed opposite somite 16 at stage 18 and the width of the limb has increased by 50%. Note the pin which held in the grafted ZPA.

region of somites 15 and 16. This shows that the ZPA can specify either digit 2 or digits 23 without formation of digit 4, and thus precludes any mechanism for specification of the digits based on sequential induction. On the contrary this result is consistent with a graded signal which specifies digit 2 when the lower part of the gradient first begins to lie within competent limb tissue. It is of interest that this result also suggests that tissues can transmit the signal without responding to it. Similarly, in a variety of other grafts where we had reason to believe that the signal from the ZPA has been attenuated by, for example, the presence of a Nucleopore or Millipore filter, it is often digit 2 only that is specified.

As the graft is placed in successively posterior positions, digit 4 develops anteriorly and a complete mirror image duplication occurs (Fig. 3b); and when placed still more posteriorly, first one digit 2 and then the other, is no longer formed between the two grafts (Fig. 3c). When the graft is opposite somites 17 to 18 only a 4334 or 434 forms posterior to the graft. When the graft is, however, moved slightly more to the posterior, contrary to expectation, no 44 combinations could ever be identified with certainty. On occasion, a small single 4 could be found. When the graft was placed opposite somites 18 and 19 at stage 18, which is quite close to the host's ZPA, normal limbs were usually formed, the digits being anterior to the graft. This suggests that the signal from the ZPA is not affected when two ZPAs are placed together. But, at stage 20 this graft often resulted in the complete absence of digit 4.

The structures formed anterior to the graft were more variable. Nevertheless, they conform quite well to the predictions of Fig. 2. Digits anterior to the graft usually only formed when the ZPA was placed opposite somite 17 or more posterior. The most common results observed were 23 and 234. At stage 18 some grafts resulted in 34 and single digits, possibly digit 4. Where a complete anterior hand 234, was present, the posterior hand was always 434 or less (Fig. 3d). One exceptional case produced 2344334, the largest number of digits we ever obtained along the same antero–posterior axis.

The results as a whole conform well with both the general and specific predictions of Fig. 2. The main deviations occurred when a single or double digit 4 were predicted in isolation. In this connection we have some evidence that a digit 4 begins to develop but fails to do so because of degeneration of the associated vascular system.

As Saunders[15] has pointed out, the grafted ZPA can bring about changes in the extent of the AER and thus the outgrowth of the limb. In fact, placing the ZPA in a variety of positions near the tip of the limb is without effect unless it is adjacent to the AER. In the normal limb the outgrowth is not symmetrical about the long axis (Fig. 4). By contrast when a ZPA is placed anteriorly (level somite 16) the outgrowth is symmetrical about the long axis, the limb increasing in width. Measurements of the change in width in operated limbs show that the increase in width seems to

correlate with the increase in number of digits obtained. From the point of view of digit specification the crucial width is that at stage 24 when the digits begin to be laid down[17]. For example, Fig. 4 shows the difference at stage 24 between a normal limb and one which had a ZPA grafted opposite somite 16. There is a 50% increase in width. It should be noted that there does seem to be a constraint on the number of digits than can be specified: this is very rarely greater than six.

Diffusion model for the signal

The predictions of Fig. 2 are based on a simple linear gradient and the question now arises whether this gradient could be provided by a diffusible morphogen. In general terms, diffusion would seem to provide a suitable mechanism particularly since the signal from the ZPA is propagated in both directions, and no discontinuities in level were found. Moreover the time/distance relationships are compatible with diffusion since the gradient is set up over about 500–1,000 μm and the time available is of the order of 10 h. It is perfectly reasonable to set up a diffusion gradient over this distance in the available time[14].

It is possible to set a linear diffusion gradient with a source and a sink at the ends[14] but in the chick wing, although the ZPA can be considered as a source, there does not seem to be any region corresponding to a localised sink. Thus it is necessary to assume the morphogen to be broken down and this will give a gradient with an exponential form. In this case the concentration of the morphogen at a given distance from the ZPA will not be constant, but will vary according to the presence of the second ZPA and this is inconsistent with Fig. 1. Ignoring the complex geometry of the limb, consider the simple one-dimensional case in which the ZPA would be the source of a morphogen which is broken down; the concentration at the ZPA being fixed (Fig. 5). If another source is now placed at the other end, analogous to placing another ZPA at the anterior border of the limb, the resulting concentration of the morphogen is as shown in Fig. 5, the concentration in the central region being considerably increased. Such a distribution is inconsistent with the results, for on any

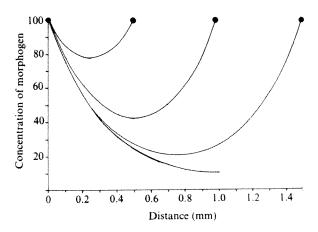
Distance (mm)


Fig. 5 The concentration profile of a morphogen for the one dimensional case, which is taken to represent the antero–posterior axis. The source (●) of the morphogen, representing a ZPA, is fixed at 100 and the diffusion constant and rate of breakdown were chosen such that, for the case of a single source, the value 1mm away from the source would be 10. The diagram also shows the profiles of the morphogen when a second source is added at varying distances along the axis. The concentration in the middle region is that most affected and is no longer that corresponding to the case of the single source. For example, when the two sources are 1mm apart, the region 0.5 mm from the ends has its concentration increased from 24 to 42. If the distance between sources is increased to 1.5 mm, however, the concentration 0.5 mm from the end is relatively unaffected.

plausible values of the concentration for specifying the digits, a graft opposite somite 16 should result in the absence of digit 2 in the middle region which is not the observed finding. But we have so far ignored the fact that when a ZPA is grafted to an anterior position the width of the limb bud does not remain constant, but increases substantially. If there is an increase in width of the distal region of the limb, the profile of the morphogen will be significantly altered (Fig. 5) since the sources are now further apart. For the highly idealised case, an increase of 50% would give a profile compatible with the results. More complex models, taking into account a homeostatic component[3] would also tend to reduce the concentration in the central region, but if the increase in width had not occurred it would have made a diffusion model very unlikely. There is in fact some evidence that cells maintain their positional value when the signal is removed, for the total removal of the ZPA and the region that will normally give rise to digit 4 leads to the loss of digit 4, but digits 2 and 3 are normal.

Our results strongly suggest that the digits in the chick wing are specified by a gradient in positional information, the nature of the digit being determined by its distance from the ZPA. The results are consistent with the specification of positional value by diffusion of a labile morphogen from the ZPA, which may be considered as a boundary region. This implies that the character of the digit is specified by a concentration gradient acting as a positional signal, but we do not know how this is read off by the cells. It should be noted that we have assumed specification of the digits to occur at the same time: it is possible to have a model in which they are specified by a series of sequential decisions (J. Lewis, personal communication). The ZPA also seems to affect the outgrowth of the limb, the width being significantly increased. This may be mediated by the

AER and the ZPA has little effect if not in contact with it.

Although we have concentrated only on digit specification here this gradient would provide the positional information along the antero–posterior axis for all elements of the limb and it is clear that the ZPA does have an effect on the proximal elements such as humerus, radius and ulna[11,14]. Moreover, it is known that a similar system is operative in the leg and the ZPA of wing and leg are interchangeable[13]. It thus shows that in the chick limb, pattern formation can occur in a way strikingly similar to that found in some invertebrates, and strengthens the view that there may be universal mechanisms. Similarities to the classical organiser may also be noted.

We are indebted to Michael Clarke for assistance with calculations on diffusion. The work is supported by the S.R.C. C.T. was a Medical Research Council Junior Fellow.

letters to nature

Local interstellar medium

NEUTRAL interstellar hydrogen can be prevented from penetrating freely into the heliosphere of solar plasma, because it is partially coupled to the subsonic flow of interstellar plasma. Results from modelling the backscattering of the diffuse Lyman-α radiation are therefore unreliable. The interstellar density of H$^+$ is probably 0.02 cm^{-3} or less, and the density of neutral hydrogen greater than 0.2 cm^{-3}.

Present thinking favours the idea that the interstellar medium in the neighbourhood of the Solar System is low density "intercloud" gas. With heating by postulated MeV cosmic rays or soft X rays, a stable state could exist[1] with atomic hydrogen density $N \simeq 0.1$ cm^{-3}, temperature $T \simeq 8,000$ K and an ionised component of H$^+$ and e$^-$ of density $n \simeq 0.03$ cm^{-3}. The plasma density might be larger because of the ionising ultraviolet emission from local hot stars[2].

Observations of Lyman-α absorption in the spectra of nearby stars indicate[3,4] generally higher values of the mean gas density $N \simeq 0.2$–0.6 cm^{-3}. The interpretation of the all-sky maps of the diffuse Lyman-α backscatter is still the subject of debate: the various models give[5-7] densities $N_L \simeq 0.05$–0.25 cm^{-3}, and streaming velocity relative to the Solar System $V = 10$–20 km s^{-1}, but are inconclusive about the temperature. Both sets of data imply that the local medium would be the low density, intercloud state, being far from the typical density 10 cm^{-3} of

clouds[1]. But if, as I argue, the density N_L within the Solar System is significantly lower than the undisturbed gas density N it seems that the local medium is not particularly close to the theoretical intercloud state.

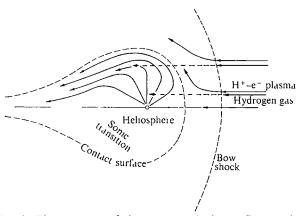
My argument is based on the global picture of gas and plasma flow in the neighbourhood of the heliosphere (Fig. 1). Two plasma shocks are shown, one terminating the supersonic solar wind and the second a bow shock[8,9], while a contact surface separates the interstellar plasma from the heliospheric plasma originating from the Sun (which acts as a source). The bow shock is a fast hydromagnetic shock and exists with the plasma parameters given earlier only if the magnetic field is rather weak: for $B < 10^{-6}$ gauss, the magnetosonic Mach number $M = V/[(B^2/\mu_0 nm) + (2\gamma kT/m)]^{\frac{1}{2}}$ can exceed unity. The plasma behaves as a fluid on a small, ion gyro-radius scale while the neutral gas moves almost freely through it. But, in practice, the gas must interact with the plasma on the large heliosphere length scale, effecting frictional drag and cooling and so distorts the flow from the standard one of a supersonic source in a supersonic stream. Indeed, the terminating shock of the solar wind is probably weak or even non-existent[10] because the plasma–gas interactions effect deceleration over an extended region, analogous to the expansion of ordinary gas into a rarefied background medium[11]. The plasma–gas interactions dominate if $B/N_L \gtrsim 10^{-5}$ gauss cm^3, in which case the heliosphere radius is[10] $R \simeq 60 N_L^{-1}$ AU (where N_L is in cm^{-3}), about twice the sonic position's mean radial distance.


Fig 1 The structure of the magnetised plasma flow in the neighbourhood of the heliosphere The streaming hydrogen gas is partially coupled to the plasma, its direct component being depleted in penetrating the diverted and shocked interstellar plasma

If the plasma–gas interactions were negligible the bow shock would stand off ahead of the heliosphere by a distance Δ, given roughly by

$$\Delta/R \simeq 1\ 1n/n' \tag{1}$$

where n' is the density downstream of a normal plane shock

$$n'/n = (\gamma + 1)/(\gamma - 1 + 2M^{-2}) \tag{2}$$

Expression (1) is applicable[12] in a wide range of values of γ and M, and even for weak shocks (see section 4 4 and Fig 6 27 of ref 13) with n'/n as low as 1 1

The main plasma–gas interaction is the resonant H^+-H charge exchange process with a cross section at 1–3 eV ($\frac{1}{2}mV^2$ or kT) of $\sigma = 6 \times 10^{-15}$ cm² I can thus estimate the proportion of streaming hydrogen atoms which pass through the stagnation region into the heliosphere as $N_L/N = \exp(- \lambda)$, where

$$\lambda \simeq (1 + v)^{\frac{1}{2}} \Delta \sigma n' \simeq 1\ 1\ (1 + v)^{\frac{1}{2}} R \sigma n \simeq 8n/N_L \tag{3}$$

The factor involving v represents the increased collision rate in thermal plasma[10] and is adequately approximated by taking $v = 0\ 7-1\ 0$ in the present situation

With the values n and N_L given above, the incoming hydrogen gas is appreciably depleted, by a factor exceeding three, and

$$N \simeq N_L \exp(8n/N_L) \tag{4}$$

exceeds 0 65 cm⁻³

This estimate is of course, very crude Particles contributing to N_L can approach laterally, avoiding the highest density stagnation region, but then pass through a larger depth of subsonic plasma, also friction of the neutral gas causes expansion of the stagnation layer and increases Δ above the value (1), and a proportion of the neutralised protons penetrate into the heliosphere and contribute to N_L Additional losses caused by interaction with the heliospheric subsonic plasma have been ignored (this latter is much hotter[10] at O (100 eV), so is less dense by a factor 100 and has little effect) But these considerations are to some extent compensatory and do not seem important enough to change the estimate (3)

Another possibility is that the interstellar field B is stronger, so that the plasma flow is sub-Alfvenic and the bow shock absent It is then necessary to calculate

$$\lambda = \int [1 + v\ (s)]^{\frac{1}{2}} n'(s)\sigma(s) ds$$

through the upstream flow, with σ larger for the smaller relative velocities and with some outer cutoff The frictional drag of the gas would distort the flow more severely, but otherwise the result for λ should not be much different from equation (3) The principal change with a larger B would probably be a decreased heliosphere radius R, but by only a factor of two for a field as strong as 5×10^{-6} gauss (ref 10)

There was an early suggestion[14] that charge exchange interactions of shocked solar wind protons with hydrogen-atoms of interstellar origin could contribute to N_L and to the diffuse Lyman-α backscatter In a curious sense, I have here reached a contrary conclusion that charge exchange processes impede the penetration of gas particles through the interstellar plasma into the solar system and reduce the local density N_L The interstellar gas is indeed not only depleted, but its thermal and streaming velocities must also be changed through the substitution of some neutralised protons Thus, analysis of the Lyman-α backscatter can tell us little directly about the real state of the local interstellar gas With the crude correction (4), the real gas density is compatible with the Lyman-α absorption values[3,4] only if the plasma density is $i \simeq 0\ 01-0\ 02$ cm⁻³ It indicates that the local interstellar gas has somewhat higher neutral-hydrogen density and lower ion density than the standard theoretical values[1]

Charged dust grains and excitation of rotational levels of interstellar molecular hydrogen

THE strengths of ultraviolet absorption lines of interstellar hydrogen have been measured in the spectra of several reddened early-type stars[1-3] Interstellar H_2 molecules are observed mainly in the two lowest rotational levels $J = 0$ ($para$-H_2) and $J = 1$ ($ortho$-H_2) with a ratio of populations corresponding to an average temperature $\sim 80\ K$ This temperature is consistent with the mean HI kinetic temperature determined in 21-cm absorption studies[4,5], whereas higher rotational levels up to $J = 5$ or 6 are populated corresponding to significantly higher excitation temperatures[3,6] in the range 150–200K These observations indicate that a process other than thermal gas collisions is responsible for populating the higher rotational levels The precise nature of the excitation mechanism is as yet unknown A process which could contribute to non-thermal excitation of rotational levels involves encounters of charged dust grains with interstellar hydrogen We have examined this mechanism and find that it could be of comparable, if not greater, importance in relation to other processes which have been proposed

Since most interstellar dust particles are believed to originate in the atmospheres of cool Carbon or Mira-type stars, the velocity of their injection into interstellar clouds is $\sim 10^8$ cm s⁻¹ (ref 7) The velocity spectrum of interstellar grains resulting from the slowing of such fast grains due to gas collisions in clouds is[7]

$$f(v)dv = A/v^2, \quad v_{max} \ge v \ge v_{min} \tag{1}$$

where A is a constant, $v_{max} \simeq 10^8$ cm s⁻¹ and $f(v)dv$ denotes the number density of grains in the velocity range v, $v + dv$ The

minimum velocity v_{min} is significantly greater than the thermal speed determined solely by thermal gas collisions Systematic dust–gas drift velocities are maintained in most regions of the Galaxy by the action of radiation pressure from integrated starlight[8,9] The total stellar radiation from the direction of the galactic bulge drives grains relative to gas at speeds $v \geqslant 10^5$ cm s^{-1} in a cloud with $n_H \simeq 10$ m^{-3} and $T \simeq 100$ K in the solar vicinity[9] In the following discussion we assume $v_{min} \simeq 10^5$ cm s^{-1} to be the minimum velocity of a typical interstellar grain The use of the distribution function (1) is strictly justified, if the slowing time of fast grains in the cloud is comparable to or greater than the residence time of grains within the cloud For a cloud of dimension ~ 3 pc, the dispersal time for grains with $v = v_{min} \simeq 10^5$ cm s^{-1} is $\sim 3 \times 10^6$ yr This is an order of magnitude greater than the characteristic stopping time of fast grains[7] Thus the concentration of suprathermal grains may have to be diluted by a factor ten below that of all grains But since charged grain acceleration mechanisms could operate in the interstellar medium the precise velocity distribution of grains remains uncertain and a larger proportion of grains may be suprathermal There is also the possibility that at least some of the clouds for which H_2 observations are available, lie in the vicinity of stellar sources of interstellar dust, so that a high concentration of suprathermal dust grains could exist In view of these uncertainties we tentatively adopt the simple distribution function (1) in the ensuing discussion The mean velocity of an interstellar grain is then

$$\langle v \rangle = \frac{\displaystyle\int_{v_{min}}^{v_{max}} vf(v)\mathrm{d}v}{\displaystyle\int_{v_{min}}^{v_{max}} f(v)\mathrm{d}v} = v_{min}\,[1 - v_{min}/v_{max}]^{-1} \ln[v_{max}/v_{min}] \quad (2)$$

$$\simeq 6\,9 \times 10^5 \text{ cm s}^{-1}$$

The role of the high energy tail of this velocity spectrum in contributing to the heating and ionisation of the interstellar medium has already been discussed[7,10] We confine our attention here to the behaviour of grains with velocities near to the estimated 'average" speed $\sim 6\,9 \times 10^5$ cm s^{-1} Such grains carry a net electric charge which corresponds to an electrostatic potential $\varphi \simeq 0\,1$ V–1 V (ref 11), and collisions of these charged grains with H_2 molecules are quasielastic with an effective cross section

$$\sigma = \pi(fa)^2 \quad (3)$$

where a is a grain radius and $f \geqslant 1$ Although the precise value of f in equation (3) is uncertain, it may be expected to exceed one by a significant factor This could arise from long-range electrostatic interaction of spherical particles as well as from the effect of surface irregularities and protrusions, such as whiskers, that may grow on grains which are in a state of rapid rotation On the basis of cross sectional data for charged radical–neutral atom interactions[12] and other considerations it seems reasonable to set $f^2 = 10$

The energy transfer to an H_2 molecule in an elastic encounter with a grain of velocity v is

$$\Delta E \simeq m_{H_2} v^2 \simeq 0\,021\,(v/10^5 \text{ cm s}^{-1})^2 \text{ eV} \quad (4)$$

where m_{H_2} is the mass of a hydrogen molecule Setting $v = \langle v \rangle = 6\,9 \times 10^5$ cm s^{-1} in equation (4) we obtain $\Delta E \simeq 1$ eV The excitation energy of the J^{th} rotational level is

$$E_J = 0\,0073\,J(J + 1) \text{ eV} \quad (5)$$

giving $E_J = 0\,31$ eV for the highest observed level $(J = 6)$ This energy is less than that transferred to an hydrogen molecule by a grain colliding with the "average" velocity given from equation (2) Charged dust grain–H_2 collisions must therefore

warrant serious consideration as a candidate for the excitation of rotational levels of interstellar H_2

The rate coefficients for the excitation of rotational levels by this process may be readily calculated For excitation of level, the rate coefficient is

$$R_J \simeq \pi f^2 a^2 \frac{\displaystyle\int_{v_J}^{v_{max}} vf(v)\mathrm{d}v}{\displaystyle\int_{v_{min}}^{v_{max}} f(v)\mathrm{d}v} [n_g/n_H]n_H \text{ s}^{-1} \quad ($$

where n_H, n_g are respectively the number densities of hydrogen and of grains, and v_J is defined by equating ΔE given by equation (4) to E_J given by equation (5) This procedure yields

$$R_J = \pi f^2 a^2 \xi\, [n_g/n_H]\, n_H \text{ s}^{-1} \quad ($$

with

$$\xi \simeq 7\,5 \times 10^5\,(1 - 0\,067\,\ln[J\,(J + 1)]) \text{ cm s}^{-1} \quad ($$

Assuming a mass fraction $\sim 0\,02$ of interstellar material in the cloud exists in the form of spherical suprathermal dust particles of density $s \simeq 1$ g cm^{-3} and radii a we have

$$0\,02 = (n_g\,4/3\,[\pi a^3 s])\,/(n_H\,m_H) \quad ($$

which may be re-expressed

$$\pi a^2\,(n_g/n_H) \simeq 2\,51 \times 10^{-21}\,(a/10^{-5}\text{ cm})^{-1} \text{ cm}^2$$

Using equations (7), (8) and (10) together with $f^2 \simeq 10$ obtain the results of Table 1

Table 1	Values of R_J*
J	$R_J\,(a/10^{-5}\text{ cm})\,/n_H$ (cm^3 s^{-1})
1	$1\,80 \times 10^{-14}$
2	$1\,66 \times 10^{-14}$
3	$1\,57 \times 10^{-14}$
4	$1\,51 \times 10^{-14}$
5	$1\,46 \times 10^{-14}$
6	$1\,42 \times 10^{-14}$

*Since all the rate coefficients vary as $\sim a^{-1}$, grains of radii 10^{-6} cm if they exist in comparable mass (as is suggested by ultraviol extinction data), would dominate the excitation processes in t present theory

For grains of radii $a = 10^{-5}$ cm the rate coefficients calculate here are of comparable if not greater magnitude than tho obtained for ultraviolet pumping (ref 13 and unpublished wo by S P T and P Joshi) for $n_H \geqslant 10$ cm^{-3} We also note th the excitation rate of the $J = 1$ level produced by the prese mechanism is greater than the para–ortho conversion ra produced by proton encounters[14] for a H$^+$/H ratio less tha 10^{-4}

In the preceding discussion it has been assumed (a) th most of the transferable energy in the encounter between an H molecule and a grain is converted into the rotational energ (b) that the excitation cross section is equal to the collision cross section, and (c) that the excitation cross section is ind pendent of the relative energy of the collision From classic considerations (a) and (b) are likely to hold true to a go approximation for quasielastic encounters between a "dumb-b type" diatomic molecule and a solid surface Experimental da on encounters between diatomic molecules and solid surfac support these statements[15] Assumption (c) is difficult to justi and could be valid only in a crude approximation Since t precise population distribution among the various rotation levels depends strongly on the validity of this assumption

more detailed quantum mechanical determination of the energy dependence of the excitation cross section is worthy of pursuit

The depopulation of levels with $J \geqslant 2$ occurs mainly by spontaneous emission, the rates of which are greater than 10^{-11} s^{-1} (ref 14) We note that this rate is much larger than the de-excitation rate of $1\ 73 \times 10^{-14}$ s^{-1} by grain collision for f^2 $t_H = 10$, $a = 10^{-5}$ cm and $\langle v \rangle = 6\ 9 \times 10^5$ cm s^{-1} Therefore, the population N_J of any level $J \geqslant 2$ may be assumed to be given by the excitation by collision of H_2 ($J = 0$) with grains followed by spontaneous decay The population of the $J = 1$ level may be governed only by grain collisions The values of N_J/N_0g_J so obtained using the spontaneous emission rates from Dalgarno and Wright[16] are given in Table 2 for different values of J

Table 2 Comparison of observed N_J/N_0g_J ratios with theoretical prediction

J	Observed N_J/N_0g_J			Theoretical (N_J/N_0g_J)
	ζ Oph	ε Per	ρ Pup	
0	1	1	1	1
1	$6\ 32 \times 10^{-2}$	$1\ 12 \times 10^{-1}$	$7\ 07 \times 10^{-1}$	$1\ 16 \times 10^{-1}$
2	$2\ 52 \times 10^{-3}$	$3\ 97 \times 10^{-4}$	$7\ 94 \times 10^{-1}$	$1\ 13 \times 10^{-4}$
3	$2\ 24 \times 10^{-5}$	$8\ 92 \times 10^{-6}$	$3\ 16 \times 10^{-1}$	$1\ 57 \times 10^{-6}$
4	$1\ 79 \times 10^{-6}$	$2\ 24 \times 10^{-7}$	$2\ 24 \times 10^{-1}$	$6\ 08 \times 10^{-7}$
5	$6\ 32 \times 10^{-8}$	$8\ 92 \times 10^{-9}$	$1\ 12 \times 10^{-1}$	$4\ 49 \times 10^{-8}$
6	$1\ 13 \times 10^{-8}$	—	—	$4\ 13 \times 10^{-8}$

The observed values of N_J/N_0g_J for three stars[6] have also been included for comparison Table 2 shows that the agreement between the calculated and observed values of N_J is not unsatisfactory for the stars ζ Oph and ε Per For ρ Pup, no agreement is possible and excitation of the rotational levels of H_2 has to be by process other than excitation by collisions with grains

Cosmological absorption of gravitational waves

SEVERAL people have investigated the absorption of electromagnetic and neutrino waves in cosmological models and discussed the self-consistency or otherwise, in the Wheeler–Feynman absorber theory of radiation, of retarded and advanced fields, a solution of the field equations is self-consistent if the absorption tends to completeness as the field propagates Cosmological absorption of gravitational waves has been treated briefly by Hawking[1] Here, the completeness or otherwise of the absorption of retarded and advanced gravitational waves will be investigated using a technique introduced, in the case of electromagnetic absorption, by Davies[2], the technique applies to the Robertson–Walker cosmologies of arbitrary spatial curvature

In a cosmological model with scale factor R, consider a wave that has angular frequency ω relative to a comoving

observer, $\omega = \omega_i/R$, a subscript i denoting the value of a quantity near the source of the wave Let t' be a time coordinate for which the metric is proportional to that of special relativity Take a time factor $e^{i\omega t'}$ and let $\varepsilon = -1$ and $+1$ for retarded and advanced fields respectively Provided the refractive index does not vary too rapidly with the radial coordinate r, the absorption factor is

$$\exp[(\varepsilon\omega_i/c) \int k\,\mathrm{d}r] \tag{1}$$

where c is the speed of light in free space, k is the imaginary part of the refractive index and the integration is over the path of the wave For fields propagating on light cones $\mathrm{d}r = -\varepsilon c\mathrm{d}t'$ and for cosmological models that are spatially flat t' is related to the cosmic time t by $\mathrm{d}t/\mathrm{d}t' = R$, so that expression (1) becomes

$$\exp(-\int \omega k\,\mathrm{d}t) \tag{2}$$

For gravitational waves, this factor is[1]

$$\exp[-(G/2c^2) \int \eta\,\mathrm{d}t] \tag{3}$$

where G is the Newtonian gravitational constant and η is the coefficient of viscosity of the medium

For atomic hydrogen $\eta \sim 10^{-4}T^{1/2}$ g cm^{-1}s^{-1} where T is the absolute temperature For fully ionised hydrogen in the absence of a magnetic field[3] $\eta \sim 10^{-16}T^{5/2}$g cm^{-1}s^{-1}

Consider absorption in a static homogeneous universe The factor (1), with $k = G\eta/2c^2\omega$, shows that appreciable absorption will occur for propagation over a range d of r where $d \approx c^3/G\eta$ If H denotes the Hubble constant of the actual Universe, then a characteristic distance in cosmology is c/H, which is about 10^{28} cm If $d \gtrsim 10^{28}$ cm, then the static model is inadequate to treat cosmological absorption In the actual Universe, observations have shown that the intergalactic medium could consist of fully ionised hydrogen with[4] 6×10^8 K$> T > 10^4$ K, corresponding in the static model to $d \sim 10^{33}-10^{45}$ cm

Suppose that all matter in the universe can be represented by a smoothed number density N Consider cosmological models of Class I in which there is continuous creation of matter at such a rate as to keep N constant, and models of Class II, in which matter is conserved so that $N \propto R^{-3}$ As an advanced wave propagates into the past its wavelength decreases and, for Class I models, eventually becomes comparable with the mean free path of the particles of the cosmic medium, then the above formulae for the viscosity are inapplicable Those formulae also fail eventually for retarded waves in Class II models, since the mean free path increases more rapidly than the wavelength When the mean free path greatly exceeds the wavelength, so that the particle collision frequency ν is much less than the wave frequency, for a non-relativistic medium[5] $k \sim N\nu T/\omega^3$

Let σ_e denote an effective cross section equal to $\omega k/Nc$ Absorption will be complete for retarded and advanced fields in the Robertson–Walker cosmologies if[2]

$$\left| \int^\infty N\sigma_e \, \mathrm{d}t \right| = \infty \tag{4}$$

and

$$\left| \int^0 N\sigma_e \, \mathrm{d}t \right| = \infty \tag{5}$$

respectively For gravitational waves expressions (3), (4) and (5) show that $N\sigma_e = G\eta/2c^2$ Take $R \propto t^n$ with $n > 0$ and consider retarded gravitational waves In Class I universes, if the temperature of the cosmic medium is constant, then expressions (3) shows that absorption is complete for all n In Class

II universes, take $k \sim NvT/\omega^3$ Also, take $v \sim NT^\alpha$ where α is a constant, thus $N\sigma_e \sim N^2 T^{\alpha+1}/\omega^2$ Suppose that $T \sim R^{-\beta}$ in the distant future From equation (4), absorption is complete if $[4+(\alpha+1)\beta]n \leqslant 1$ Davies[2,6] investigated the thermal future of the universe by considering the interaction of the intergalactic medium with the cosmic electromagnetic blackbody background radiation He showed that for models that expand more slowly than $t^{1/2}$, the intergalactic plasma eventually completely recombines, for models that expand more rapidly than $t^{1/2}$, the plasma does not completely recombine and remains coupled to the electromagnetic background radiation If the intergalactic medium eventually recombines, then $\alpha = 1/2$ and $\beta = 2$, if the medium does not recombine, then $\alpha = -3/2$ and $1 \leqslant \beta \leqslant 2$ Thus, absorption of retarded gravitational waves in Class II universes is complete if $n \leqslant 1/7$

Now consider advanced gravitational waves Assume that σ_e approaches a constant as $\omega \to \infty$ In Class I universes, expression (5) shows that absorption is finite for all values of n In Class II universes with a "hot big-bang", as they travel into the past, advanced waves that are not absorbed first eventually enter an epoch in which the cosmic matter is in thermal equilibrium with electromagnetic radiation at relativistic temperatures As this epoch is entered there is a rapid increase in N because of thermal electron–positron pair production[7], within this epoch the mass density of the cosmic medium varies as R^{-4}, but N still varies as R^{-3} Thus full absorption of advanced waves occurs for $n \geq 1/3$

Consider now condensed objects, and suppose that their interaction with gravitational waves can be represented by a constant σ_e Suppose that in Class I universes there is a constant number density of such objects for retarded waves absorption is complete, for advanced waves, absorption is finite Suppose that in Class II universes the number density of condensed objects varies as R^{-3} in the distant future absorption of retarded waves is complete for $n \leqslant 1/3$

Assume, for the sake of argument, that the absorber theory of radiation is valid for gravitational waves, that only retarded gravitational waves can be observed in the actual universe and that σ_e saturates at high frequencies In determining what cosmological models are to be eliminated, with these assumptions, as possible models of the Universe, the relevant values of n are those applicable for $t \to 0$ and for $t \to \infty$, such values will be denoted by n_0 and n_∞ respectively No Class I universe with the characteristics taken above is eliminated Class II universes with $n_0 > 1/3$ are eliminated Class II universes with $n_\infty > 1/3$ are eliminated In the standard "hot big-bang" model of general relativity, $n = 1/2$ in the radiation-dominated epoch so that this model has consistent advanced fields and is eliminated In the spatially flat case of the Brans–Dicke cosmology, $n = (2\omega_{BD}+2)/(3\omega_{BD}+4)$ where ω_{BD} is a parameter, with[8] $\omega_{BD} \geq 0$ it follows that $1/2 \leqslant n \leqslant 2/3$, where the upper limit corresponds to the Einstein–de Sitter universe of general relativity these models are eliminated since retarded fields are inconsistent The Friedmann models with zero cosmological constant and negative spatial curvature have $n_\infty = 1$ and are hence eliminated

Of course, these eliminations are purely hypothetical, being based on the three assumptions mentioned above If cosmological observations were to establish one of these hypothetically eliminated models as a reasonable model of the Universe, then that result would constitute evidence against at least one of the assumptions

Solar test of Dirac's large numbers hypothesi

DIRAC[1,2] has proposed that the large dimensionless numbei that are constructable from the fundamental constants c physics and astronomy are related to each other, and ai simple functions of our present epoch in the Universe Thus h suggests that, as measured by atomic standards, the gravita tional constant, G, varies with the time as t^{-1} and the number c nucleons in the Universe increases as t^2 In more recent work[3,] he has pursued the consequences of assuming different mode of creation of new matter We have found that Dirac's theory c multiplicative creation, but not his theory of additive creatioi is not in contradiction with known facts about the Sun

By "additive creation" he implies that matter is forme uniformly throughout space, and therefore mostly in inte, galactic regions, the mass of a small object like a star woul remain essentially unaltered by the new creation of matte "Multiplicative creation" means that existing matter multiplie itself in proportion to the amount of matter already present therefore the mass of a star, M, would grow as t^2

In view of the important cosmological consequences c Dirac's theory, it is desirable to test it with methods present available One useful test object is the Sun The proposed larg change in G over the Sun's past lifetime and, with multiplicativ creation, the concomitant large change in the Sun's mass, woul be expected to produce a different evolutionary history for th Sun as compared with the 'standard' history computed on tl basis of constant G and M But with any theory the observab properties of the Sun today (mass, luminosity, and radiu must be achievable with 'reasonable' choices of initial chemic composition Unfortunately, the chemical composition of th present surface layers, which presumably reflect the origin composition, is known only with great uncertainty, and th allows a considerable latitude of choices A further constrair (and a possible benefit that could accrue from a 'non-standar theory) is the small solar neutrino flux that is observed and not explained by 'standard' theories

The one 'free' parameter in Dirac's theory is the age of tl Universe, t_0, although observations of the Hubble constant p some limits on it If t is measured from the time of formatic of the Sun, then

$$G(t) = G_0 \left[\frac{t_0 - t_\odot + t}{t_0} \right]^{-1}$$

and

$$M(t) = M_0 \left[\frac{t_0 - t_\odot + t}{t_0} \right]^n$$

with $n=0$ for additive creation and $n=2$ for multiplicati creation At the present epoch, $G_0 = 6\ 67 \times 10^{-8}$ cm^3 g^{-1} s $M_0 = 1\ 99 \times 10^{33}$ g, and $t_\odot = 4\ 5 \times 10^9$ yr

The hypothesis of additive creation has already been tested Pochoda and Schwarzschild[5] They found that this hypothe can be satisfied if $t_0 \geqslant 15 \times 10^9$ yr Today, such an age for th Universe is certainly admissible, although it seemed rather long a decade ago But the required initial hydrogen conte $X = 0\ 81$, seems somewhat high Moreover, the predic brightness of the Sun in the past, in spite of the greater dista

of the Earth from the Sun then (in the additive theory), may conflict with palaeontological evidence[6] One further consequence of the additive theory is particularly relevant here the hydrogen content near the centre of the present Sun must be completely exhausted Although Pochoda and Schwarzschild did not publish any temperatures, the central temperature of their final model is probably about 19×10^6 K (see, for example, ref 7) In these conditions the expected neutrino flux must be enormous—several orders of magnitude greater than the upper limit of the neutrino flux measured by Davis[8] But it should be borne in mind that standard solar models themselves predict a neutrino flux that is about an order of magnitude larger than Davis's upper limit of 1 SNU

In order to test Dirac's hypothesis of multiplicative creation, we have evolved several sequences of stellar models up to the present age and mass of the Sun It has been assumed that, since the solar gases are highly ionised, new ions (and a corresponding number of electrons) are created in the vast empty spaces between the existing particles They are assumed to be of the same species as their 'parent' ions Moreover, they must share the same kinetic energy and linear momentum as their neighbours, on the average, and therefore units of kinetic energy and momentum (including units of rotational angular momentum of the whole Sun) must also be created Dirac has already postulated these conditions for the Earth, in order not to contradict geological evidence For our purposes, it is sufficient merely to scale up the chemical structure of the evolving solar models as the mass of the Sun is increased For simplicity, axial rotation of the Sun is neglected

The other physical input parameters are the same as those used in previous work[9] To summarise them here for convenience, we have adopted the new Carson (unpublished) opacities, which are very close to those of Cox and Stewart[10] for main-sequence stars of low and intermediate masses, the nuclear cross sections of Bahcall, Bahcall and Ulrich[11], but with the neglect of the *pep* reaction, a ratio of mixing length to pressure scale height in the outer convective envelope equal to $\alpha = 2$, and a metals abundance of $Z = 0\,015$ Results for the initial and final solar models are given in table 1 We have found that the final radius does not agree exactly with the observed radius, for the choice of $\alpha = 2$ But, as many people have shown a suitable change of α can achieve agreement between the radii without significantly altering the luminosity, which is affected primarily by the choice of initial chemical composition Therefore, we have not considered it worthwhile to rerun the sequences with different guesses for α until the final radii are correct

The standard solar model obtained here is very similar to the analogous one already calculated by Carson, Ezer, and Stothers[9] The two models are not identical because we have here adopted equilibrium nuclear reaction rates and a slightly different treatment of the thermodynamical quantities, apart from the fact that the computer program itself is different

Turning now to the final solar models based on Dirac's multiplicative theory, we find the rather surprising result that they are nearly the same as the final model based on standard

theory[1] This occurs in spite of the widely disparate initial masses, occasioned by the use of a full range of choices for t_0 The reason for this similarity is that the effect of a larger G in the past is to increase the luminosity[6], whereas a lower stellar mass decreases it As a result of these compensating factors, the ratio L/M remains approximately constant Since the nuclear reaction rate and the amount of hydrogen depletion depend on the L/M ratio[12], the final central temperature and the final hydrogen profile throughout the Sun are about the same as they were in the standard case

Since the radius, r, of the Earth's orbit around the Sun increases, in Dirac's multiplicative theory, as t, the temperature of the Earth's surface may be expected to change like $(L/r^2)^{1/4}$ ~ constant This naive prediction is not in contradiction with palaeontological evidence But why are well-preserved Precambrian and early Cambrian fossils in essentially perfect shape if their masses have increased by a significant percentage?

One could pursue the test of Dirac's theory by constructing theoretical isochrones for old clusters containing stars of low mass and comparing them with observed cluster H–R diagrams Although we have not done this, it is interesting that the more massive members of this old population must have evolved long ago—mostly into white dwarfs, initially But since the upper mass limit for a stable white dwarf (or neutron star) is proportional to $G^{-3/2} \sim t^{3/2}$, and since the mass of the star itself increases as t^2, eventually these stars will all undergo gravitational collapse The galactic halo must be popping with continually forming black holes The ultimate cosmological consequence is a universe full of gravitationally collapsed objects

We thank V Canuto and P A M Dirac for discussions, and T R Carson for permission to use his unpublished stellar opacities

Age and rates of denudation of Trap Series basalts at Blue Nile Gorge, Ethiopia

BETWEEN Lake Tana and the Sudan border the Blue Nile has cut a deep gorge across the Ethiopian Highlands The first 150 km of its course lies on lavas of the Tertiary Trap Series, after which the river flows through horizontal Mesozoic and Palaeozoic sediments until the Precambrian is reached 330 km from Lake Tana[1] About 280 km below the lake the Addis Ababa–Debre Markos road crosses the gorge at 10° 05'N, 38° 10'E, where 250 m of Trap Series basalts overlie at least 1,150 m of sediments the base of which is not exposed The gorge is 1,400 m deep and 20 km wide and is incised into a plateau 2,600 m high

On the south side of the gorge the Trap Series section comprises at least five thick horizontal flows of aphanitic basalt, belonging to the lower part of the Trap Series as a whole The top three flows are well exposed and each is several tens of metres thick and extends laterally for over

5 km These features suggest that the flows were the product of fissure eruptions[2]

Grasty et al[2] tried to date the flows, but their results were inconclusive We have dated fresh samples from the top four flows (Table 1), using techniques described previously[3] It was not possible to obtain samples free from interstitial glass or mesostasis, and the possibility of argon losses must be taken into account when interpreting the results, notably the low age obtained for the third flow Nevertheless, the close agreement in ages obtained suggests strongly that they are near the truth, and that the actual age of the basalts is certainly less than 30 Myr This age is similar to the ages obtained[4] from the lower part of the Trap Series elsewhere in Ethiopia

The dating of these horizontal flows gives a lower limit to the age of incision by the Blue Nile into the uplifted Ethiopian highlands Merla[5] considered that uplift occurred in two stages one in the Miocene, and the other in the Plio–Pleistocene with the development of deep canyons, including the Blue Nile and Tekezze (Atbara) gorges The overall rate of erosion since the deposition of these basalts may be calculated by two methods One is to find the volume of sediments derived from the upland Blue Nile and Tekezze basins and deposited in the Gezira and Atbara fans, along the main Nile and in the Nile Delta The other is to calculate the volume of rock eroded from the uplands themselves

At present the White Nile provides less than 2% of the annual sediment load of the main Nile[6], and the high proportion of Ethiopian minerals[7] and pollen[8] in Nile deltaic sediments indicates that a similar situation obtained during at least part of the Cainozoic Various estimates of the volume of sediments comprising the Nile Delta have been made[9,10], but taking into account seismic work[11], a figure of between 100,000 and 200,000 km^3 seems reasonable The volume of alluvium along the main Nile flood-plains and terraces between Khartoum and the delta is not known, but an estimate of between 100 and 600 km^3 can be made The Gezira Plain between the Blue Nile and the White Nile south of Khartoum is a low-angle alluvial fan built up mainly by the Blue Nile[12] Isopach values[13] indicate a volume of about 1,800 km^3, which excludes probable White Nile alluvium A rough estimate of 800 km^3 may be made for the volume of the Atbara Fan, given its smaller catchment area relative to the Blue Nile

The total volume of material deposited by the Blue Nile and Atbara (Tekezze) in Egypt and Sudan is, therefore, estimated at between 98,000 and 225,000 km^3, the bulk of which forms the Nile Delta For simplicity we here assume a value of $150,000 \pm 50,000$ km^3, derived mainly from Ethiopia The areas of the two basins in upland Ethiopia above 1,000 m are 190,000 and 85,000 km^2, respectively Allowing for the difference in bulk density between Nile deltaic sediments (about 1 5 g cm^{-3}) and the eroded Ethiopian bedrock (about 2 8 g cm^{-3}), and assuming a 30% loss in solution from the Ethiopian uplands, the mean erosion rate over the past 23 5 Myr would be 12 ± 6 m^3 km^{-2} yr^{-1}

This result may be compared with that obtained by calculating the volume of rock eroded from the two basins, using a contour map of the highlands The dissected plateau has a mean local relief of about 1,500 m and a mean surface elevation of about 2,500 m The estimated volumes of rock removed from the Blue Nile and Tekezze basins are 71,000 km^3 and 31,000 km^3, respectively That gives a total of 102,000 km^3, to an accuracy of about 50% As the area of the basins is about 275,000 km^2, the mean rate of denudation must have been $15 \pm 7\ 5$ m^3 km^{-2} yr^{-1}

Such denudation rates of around 0 015 mm yr^{-1} are very low for a tectonically active region of high relief[14–18], they are more in keeping with modern rates from undisturbed, forested, tropical lowlands[19–21] Modern erosion rates in the region are far higher, with estimates of the Nile sediment load at Cairo ranging from 57 to 120 Mt yr^{-1} (refs 6, 22 and 23) These estimates show a doubling of sediment load during the past 70 yr[23,24], reflecting accelerated erosion of the headwaters If an annual sediment load of 50–100 Mt is derived from Ethiopia, the present rate of erosion in the headwaters of the Blue Nile and Tekezze must be about 120–240 m^3 km^{-2} yr^{-1}, or an order of magnitude greater than the overall geological rate

The discrepancy between the two rates suggests episodic uplift interspersed between prolonged stable intervals Faure[25] calculated the rate of uplift of the plateau to be 0 5–1 0 mm yr^{-1} during the Upper Pleistocene, compared with a mean rate of 0 1 mm yr^{-1} since the Middle Tertiary We conclude that a change in the rate of uplift of that magnitude, coupled with recent deforestation of the head-waters, can explain adequately the difference between the modern and geological erosion rates It may be further noted that the close agreement between the volume of material eroded from Ethiopia, and the volume in the Nile Delta, is further evidence suggesting that the bulk of the Nile deltaic sediments are of Ethiopian provenance

We thank M F Clarke for critical comments

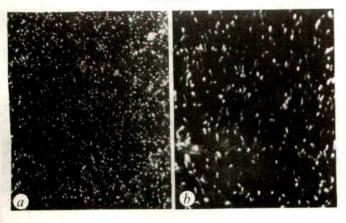
Non-etching optical detection of fission tracks using Teflon


THE detection of tracks in material irradiated by charged particles, has been accomplished using electron microscopy[1] and etching followed by optical microscopy[2-6]. We have attempted to detect unetched tracks using optical microscopy. Presumably, unetched tracks retain more information about the radiation than is retained after etching.

The kinds of damage which can be caused by the passage of a charged particle through any material are bond ruptured, which produces free radicals[7], physical dislocations, as in the Wigner effect in reactors in which carbon atoms in graphite are displaced by fast neutrons, and certain other less obvious but more visible effects such as the production of metastable states which emit light, as in thermal luminescence and scintillation counters.

It seemed possible that, in order to obtain the best record of the track itself, a material and detection process could be used which would minimise the general background and make possible the direct observation of the track itself using an optical microscope. So we chose, following the work of others[8-12], to use cross linkage copolymerisation of radiation-damaged polytetrafluoroethylene, Teflon, with acrylic acid monomer followed by dying with the basic dye Rhodamine B which phosphoresces in orange under exposure to blue light. Teflon is one of the most chemically resistive materials known and should give essentially no background.

Teflon plastics films (51, 127, and 762 μm thick) were irradiated in air with fission products from a 50 μCi ^{252}Cf source for 1–2 min at room temperature. The samples were then inserted into glass tubes containing acrylic acid solution and degassed by freezing and pumping the system

Fig. 1 Tracks of fission fragments. *a*, × 180 diameters; *b*, × 360 diameters. Made by grafting acrylic acid on to Teflon. The apparent length of each track is related to the angle of its inclination.

several times. After degassing, a grafting reaction with the free radicals in the tracks was allowed to continue in the absence of air at controlled temperatures (23–40 °C), for varying times (5–30 h). Good grafting was obtained at 23 °C after 25 h or at 40 °C after 5 h. We were also successful in getting good grafting results when the reactions were carried out in a dry nitrogen atmosphere. In these experiments dry nitrogen gas was bubbled through the acrylic acid solution for 15 m and then the tube was closed. Grafting occurred in dry nitrogen under conditions similar to those used in the evacuation experiments.

The solution was 50 % vacuum distilled acrylic acid ($CH_2.CH.COOH$). After the grafting, the Teflon samples were washed thoroughly in deionised water at 50 °C for 2 h. Following this they were dyed with a boiling 3 % solution of Rhodamine B for several hours and then washed for 15 min in a 2 % acid soap solution to remove any unfixed dye. This procedure was apparently successful: the basic dye fixed itself to the acidic polymer that was attached to the damaged area of the Teflon.

Finally, the samples were examined with a Reichert-Austria Zetopan microscope fitted with an ultraviolet lamp. Rhodamine B phosphoresces with an orange colour when illuminated with light at a wavelength of 400 nm. A cutoff filter eliminated the excess blue light which produced a dark field, and the fission tracks then appeared as bright lines (Fig. 1a and b).

It seems possible that more information can be obtained from tracks developed and measured in this way and that Teflon treated like this may well be useful in the future detection of tracks formed by the passage of charged particles.

Rapid hydrogenation of sterols in a contemporary lacustrine sediment

THE steroid carbon skeleton has been widely used as an indicator of biological origin of the organic material in ancient sediments[1-3] and petroleum[4]. Sterols, presumed precursors of the geolipid steranes, and stanols, their saturated analogues, have been identified in Recent[5-7] and ancient[8,9] sediments. In view of their generally low abundance in living

organisms, the presence of stanols in Recent sediments suggests the operation of a sterol hydrogenation process early in the geological time scale. We have sought to confirm this hypothesis by examination of the contemporary sediments of Rostherne Mere, Cheshire, England. The sterol composition of the sediment, and its variation with depth, provide circumstantial evidence for the hydrogenation of Δ^5-sterols[10]. Here we describe the application of radiochemical techniques[11,12] to the study of the early diagenesis of cholesterol (cholest-5-en-3β-ol) in Rostherne sediment and report the first direct evidence of rapid sterol hydrogenation in a geological environment. The sediment chosen for study is that of a highly productive lake. Significant allochthonous (land-derived) organic input to Rosterne Mere has been exceeded in recent years by an increasing autochthonous production of blue-green algae[13,14]. The sediments in the deepest part of the lake (from where samples were taken) remain severely depleted in oxygen throughout the year[15]. As a National Nature Reserve, Rostherne Mere is protected from gross pollution, though there is some chemical evidence to suggest a recent input of petroleum-derived material[14].

4-[14]C-cholesterol (Radiochemical Centre, Amersham) was purified by thin-layer chromatography on silica gel and on silver nitrate impregnated (30% by weight) alumina (Ag$^+$TLC)[16], to remove traces of [14]C-stanols. Incubations with 4-[14]C-cholesterol were conducted both in sediment cores from Rostherne Mere and in the model environment of anaerobic sewage sludge. Sediment cores (50 cm × 6 cm), encased in Perspex tubes, were taken intact from the deepest part of Rostherne Mere. For laboratory incubation, the core was stored in a polystyrene container, over a small quantity of dry ice, during transport to the laboratory. A second sediment incubation involved injection of 4-[14]C-cholesterol and suspension of the core in the lake near the sediment–water interface for the duration of the incubation. The "zero time" incubation, in which acidification and extraction (heptane–isopropanol) immediately followed injection of radiolabel, enabled an assessment of purification and work-up procedures. Further experimental details are given in Tables 1 and 2; a full discussion will be provided elsewhere (S. J. G. and G. E., in preparation).

Table 1 summarises the sterol constituents identified in Rostherne sediment. Examination of the variation in sterol composition indicates an increase in the stanol to Δ^5-sterol ratio with sediment depth (ref. 10 and S. J. G. and G. E., in preparation). For the 0–10 cm sediment level, examined in conjunction with a labelling experiment (A, Table 2), the carbon number distributions of the Δ^5-sterol, 5α-stanol and

"Δ^5-sterols", "5α-stanols" and "5β-stanols" obtained from crude total sterol fraction by Ag$^+$TLC. Radiolabelled stanol products of incubation characterised by radio-TLC, radio-GLC and GC–MS (S.J.G. and G.E., in preparation). Other radiolabelled products uncharacterised or not fully characterised; see text.
§ Not determined.
¶ Radioactivity not detected above background.

5β-stanol constituents are similar, confirming the earlier findings[10]. The presence of large quantities of stanols, relative to unsaturated sterols, together with the parallel distributions of saturated and unsaturated analogues provides strong evidence for the operation of an hydrogenation process in the young Rostherne sediment.

The results of radiolabelling experiments are summarised in Table 2. The incomplete recovery of radiolabel in the zero time incubation experiment D emphasises the difficulty of quantitative extraction of sterols. The particularly low recovery in experiment B, where incubation was conducted in the lake, may be attributable to losses at the flocculent sediment–water interface. In sediment incubations, unchanged [14]C-cholesterol was the major labelled product but sewage incubation (experiment C) yielded a major fraction (31% of injected radioactivity) corresponding in polarity to unsaturated steroid ketones (see below). Each stanol fraction, obtained by Ag$^+$TLC, was subjected to a second Ag$^+$TLC separation to ensure absence of [14]C-cholesterol. The "5α-stanol" TLC fraction from zero-time incubation (D, Table 2) contained no detectable activity. The origin of the small quantity of activity in the "5β-stanol" fraction is uncertain but may arise from TLC overlap with products of sterol dehydration during the work-up procedure. The levels of activity in the stanol fractions from sediment and sewage incubations (A and C, Table 2), however, indicate clearly that both 5α- and 5β-stanols are genuine products of incubation. In experiments A and C, analyses by radio-gas chromatography and combined gas chromatography–mass spectrometry (GC–MS) established [14]C-5α-cholestanol and [14]C-5β-cholestanol as the sole radiolabelled components of their respective fractions. The 5α-isomer predominated, both as a radiolabelled product of incubation and as a natural constituent, in the sediment incubation whereas 5β-cholestanol was the more abundant in sewage sludge.

In both sediment and sewage incubations, other labelled products of incubation included components whose TLC mobilities were consistent with saturated and unsaturated steroid ketone structures. Radio-gas liquid chromatography (GLC) analyses with coinjection with authentic standards suggested the presence of [14]C-cholest-4-en-3-one, [14]C-5α- and [14]C-5β-cholestanone. This evidence suggests that the hydrogenation of the Δ^5 double bond in cholesterol, effective in sediment and sewage sludge, may be a biochemical process for which the mechanism is similar to that observed to be

¶ Tentative assignment.

operative in certain bacterial[19,20] and other biological systems[21,22].

We believe that the results of the radiolabelling experiments with [14]C-cholesterol in Rostherne sediment provide a clear indication of an hydrogenation process taking place in the sediment under environmental conditions, for the following reasons. First, the radiolabelling results are consistent with the indirect evidence for a sterol hydrogenation process based on sediment lipid analyses. The relative amounts of Δ^5-sterols and 5α-stanols (in approximate ratio 1:2), as natural sediment constituents, suggest a conversion of approximately 60% during the period of deposition of the 0–10 cm sediment layer (about 20 yr), indicating an average rate of hydrogenation approximately equal to that observed in the labelling experiment (A) (that is, 0.5% in 3 months).

Second, the specific activities (determined by radiocounting and GLC quantitation, with an internal standard) of radiolabelled 5α-cholestanol and 5β-cholestanol, following incubation of [14]C-cholesterol in Rostherne sediment (experiment A) were the same (0.11 μCi mg^{-1}).

Third, incubation of [14]C-cholesterol in a sediment core, suspended in the lake for the duration of the incubation (experiment B), also indicates conversion to radiolabelled stanols.

These experiments have demonstrated that the geochemically significant hydrogenation of naturally-occurring unsaturated sterols, to give both 5α- and 5β-stanols, may be effected extremely rapidly in contemporary aquatic sediments. The presumably microbiological process may be analogous to that observed in other biological systems with the consequent 5α- : 5β-stanol ratio dependent on the particular microbial population (compare the results of [14]C-cholesterol incubation in anaerobic sewage sludge).

We thank the Nature Conservancy for permission to take samples and perform experiments in Rostherne Mere and Mr D. Rogers, Warden at Rostherne, for assistance. We are grateful to Mr G. Hall, Avonmouth Foul Water Treatment Works, for provision of the sewage sludge sample. This work was supported by the Natural Environment Research Council, the National Aeronautics and Space Administration and the Nuffield Foundation.

The hipparions of the Baringo Basin sequence

THE first appearance of Hipparion in land mammal populations of the northern hemisphere is one of the best documented biochronological events of the Neogene: the genus appeared first in the Mediterranean world about 12.5 Myr ago[1]. In France[2] its first appearance was during the Middle–Upper 'Helvetian' (ante-'Tortonian'). New radiometric information from the Far East supports an age of 10.5 Myr for the base stratotype Tortonian[1]. This means that the Hipparion datum of 12.5 Myr is some 2 Myr earlier than the advent of the Vallesian.

In North Africa the earliest Hipparion is the same as the primordial Old World Hipparion primigenium (Von Meyer) of the 'Pontian' (Vallesian and Pikermian) of Europe. It was described as Hipparion africanum Arambourg[3] from the Vallesian of Wad el Hammam in Algeria[4]. H. primigenium also occurs in the Tortonian Beglia Formation of Tunisia[5].

In Asia, Hipparion appeared first in the Nagri Formation of the Siwaliks[6] about 10–12 Myr ago. Hussain described the Nagri Formation Hipparion as Hipparion nagriensis[7]. Although the skull is unknown, H. nagriensis seems to be a clear synonym of Hipparion primigenium: the cheek teeth are of the same size and have the very characteristic pattern of this species (see ref. 7 plates 1 and 2, and ref. 8 Figs 21 and 22). Hussain noted the resemblance of H. nagriensis to Hipparion catalaunicum Pirlot and H. koenigswaldi Sondaar[7], both of which are synonyms of H. primigenium[4].

In the summer of 1973 I received the Hipparion remains from the Ngorora Formation in Kenya, which is between 12 and 9 Myr old[9] (see also ref. 10). Before this discovery, it was thought that the earliest Hipparion south of the Sahara was in the Mpesida Beds of Kenya, dated at 7 Myr, terminal Pikermian[9,11]. The Hipparion from the Mpesida Beds is the same as that from Lothagam–1 in the Turkana District on the west side of Lake Rudolf in Kenya, age 6 Myr. It has been described as Hipparion turkanense[12,13].

The Ngorora Hipparion is very different from H. turkanense but is indistinguishable from Hipparion primigenium. Hipparion primigenium also occurs in the Chemeron Formation (locality J.M.493), at Kanapoi, and in the Aterir Beds. On the other hand, teeth indistinguishable from H. turkanense are found in the Kaperyon Beds. Thus, it seems that there are two large species of Hipparion in the Baringo Basin sequence: H. primigenium emerging in the Ngorora Formation, and H. turkanense in the Mpesida Beds, representing a later invasion from Asia. The two species survived till the 4 Myr level, for teeth indistinguishable from those of H. turkanense are found at Kanapoi and in the Mursi Formation of southern Ethiopia. With the discovery of Hipparion primigenium in the Ngorora Formation it has been settled that there is not so much of a time lag between the first appearance of Hipparion south of the Sahara and that north of the Sahara as had been supposed previously. One species only, Hipparion primigenium (Von Meyer), first appears to be distributed over much of the Old World, not only in Eurasia but also in Africa both north and south of the Sahara in the Vallesian.

Distribution of hydrogen bond angles in molecular crystals

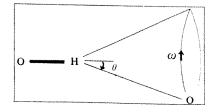
THE structures of hydrogen-bonded molecular crystals have been studied extensively, and the resulting histograms of the distributions of the O–H $\cdots$ O bond angles θ show maxima at approximately 15° from the linear configuration[1-3]. At first sight this seems odd, because theoretically a linear hydrogen bond is stable[4,5]. Kroon and Kanters[3] have indicated, however, that because the number of possible hydrogen bond configurations at any value of θ is proportional to $\sin\theta$, these histograms should not be interpreted to indicate that the configuration of $\theta = 15°$ is, energetically, the most stable. They applied the $\sin\theta$ correction to the statistics of a series of 196 values of hydrogen bond angles in molecular crystals, and showed that the experimental distributions are not inconsistent with an assumed preference for linear hydrogen bonds.

One of us (M.H.)[5] has calculated the potential energy function for the bending of the hydrogen bond O–H–O $\cdots$ O–H$_2$ using the method of CNDO/2, one of the semi-empirical LCAO MO SCF methods which includes all the valence electrons. We intend to show here that the histograms of Kroon and Kanters[3] can be explained by Hasegawa's[5] potential energy function.

The potential function[5] can be represented approximately by the following quadratic form:

$$\Delta E = s\theta^2/2 \tag{1}$$

in which the linear hydrogen bond is most stable and ΔE represents the strain energy for the bending through θ degrees of the hydrogen bond. The value of the force constant, s, is estimated at $0.4\,\text{eV}/\text{rad}^2$. In the case of the hydrogen-bonded water dimer, the dependence on the angle ω of the strain energy ΔE is small, so that factor is neglected here.

If it is assumed that the distribution among configurations in various molecular crystals may be approximated by a Boltzmann distribution, the distribution function $f(\theta)$ for the bending of the hydrogen bonds is represented by


$$f(\theta) = C \sin\theta \, \exp(-s\theta^2/2kT) \tag{2}$$

where C is the normalisation factor, k is the Boltzmann constant, and T is temperature, taken to be 300 K. The factor, $\sin\theta$, is necessary because the number of possible configurations at a given value of θ is proportional to $\sin\theta$ and the energy dependence on ω is neglected.

The histogram for the distribution of the O–H $\cdots$ O hydrogen bond angles can be calculated using this procedure (Fig. 2).

Figure 2 also shows Kroon and Kanters's histogram[3] of 196 O–H $\cdots$ O hydrogen bond angles observed in molecular

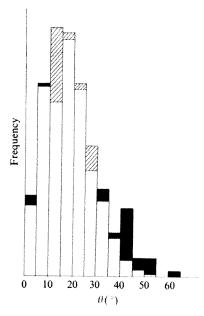
Fig. 1 A bent hydrogen-bonded configuration.


Fig. 2 The superimposed histograms of the theoretical and experimental distributions of O–H $\cdots$ O hydrogen bond angles. The experimental histogram is from Fig. 2 of ref. 3. Excess of experimental frequency over theoretical frequency is indicated by solid shading and excess of theoretical frequency over experimental frequency is indicated by hatching. Thus, open column indicates the amount of frequency common to both theory and experiment.

crystals. The two histograms agree quite well with each other: in our calculation the distribution shows a maximum at 14.5°, and the maximum from the molecular crystal data is approximately 15°. The slightly narrower distribution of our theoretical histogram compared with the experimental histogram may be because of the omission of the higher order terms in the right hand side of equation (1).

The hydrogen bond angle is a factor of the molecular structure and molecular arrangement in each crystal. The fact that the distribution of θ, found when the values of the hydrogen bond angle in various crystals are treated statistically, coincides with the distribution for an isolated hydrogen bonded structure, seems to suggest that the perturbation experienced by a structure of O–H $\cdots$ O in molecular crystals is very small.

Marks of unknown carbonate-decomposing organelles in cyanophyte borings

BLUE-GREEN algae are a major agent of destruction of carbonate rocks and sediments, particularly in the littoral and shallow marine environments. The organisms discussed here are endolithic, that is, the individual algal filaments reside snugly in made-to-measure tunnels of their own, excavated chemically. Data presented here suggest that much of this geologically significant bioerosion is actually caused by what may be called digestion of the mineral substance, and is not

Book review supplement

IN spite of recent advances in the study of the history of education, many important tendencies and crucial decisions have never been fully explored. There is also a dearth of good biographies. The intelligent and industrious partnership of Ashby and Anderson has now provided, however, a lively and valuable contribution to this field. Their book is scholarly and compact and is based on a careful examination of a mass of scattered evidence.

Haldane was a front rank Liberal politician, more remembered for his army reforms than for his educational activities. Even his own autobiography has relatively little to say about education. Yet he was concerned throughout his life more with education than with any other topic and with the ends of education as much as with the means. He placed it in the forefront both of industrial progress and of democratic politics, and with a rare combination of psychological and political skills initiated or participated in many practical educational enquiries and enterprises. The very range of his activities and the extent of his commitments make his occasional failures as interesting and significant as his many successes, and the decisions which were not taken as a result of his advice or actions are as worthy of thoughtful investigation as the decisions which were.

Haldane believed profoundly in the unity and continuity of education—including adult education about which he had much to say. He also believed in a bigger place for science and technology within university institutions.

No one emphasised more than he the need for 'system' in education, yet he conceived of that system in organic and not in mechanical fashion : everything educational was part of the same "organic whole", from nursery schools to Workers Educational Association classes. It followed from this approach that universities were not separate

Visions of Haldane
Asa Briggs

institutions with their own vested interests but necessary elements—differentiated perhaps in styles—of 'national education', the development of which was successful "in proportion as it is guided by a policy which regards it in all its bearings and aims at settled objects". In practice, few educational institutions, except new ones, have ever approached national education quite in this way, and Haldane himself, who

chose his arguments to suit his audiences, would have been unsuccessful had he not been an indefatigable as well as a clever manipulator and, above all, "a great public personage".

Ashby and Anderson explain well how his approach, shaped by German philosophy and operated through well selected manoeuvres, affected the emergence or development of particular institutions — among them Imperial College and the University of Liverpool—and of the University Grants Committee as the guardian of the 'system'. Their conclusion is well balanced. They recognise that even without Haldane's personal contribution, much of what has subsequently happened in higher education in this country would have happened anyway. Yet without him, they add, "the style and tenor" of what has happened would have been different and "poorer". His conceptions were not original but through his own efforts they were "institutionalised". Of course, this only applies to some of them. When the Robbins Committee turned to structures in higher education years later, it referred to "a system if it can be called a system". The 'binary system' Haldane would have deplored—though all its outlines were there before he died—and there is still no 'system', even in an embryonic form, in adult education in spite of the valiant efforts not only of Haldane but also of Ashby.

It is possible to discern in the well organised pages of this biography sketches of alternative notions of education, deliberately less systematic or even non-systematic, for Haldane

always had his critics. He once wrote to Joseph Chamberlain mentioning "Oxford notions of what a University ought to be", and there would certainly have to be taken into account if this portrait of Haldane were to be expanded into a monograph on continuity and change in British higher education. The very idea of 'system' offended some critics, and the German philosophical language in which it was often expressed (sometimes with dangerous political potential) offended more.

Given a systematic approach in a country where it is easy to spurn enthusiasts in education as well as logic, what obviously counted then, as now, was the quality of the people making the key decisions concerning its operations and planning. Haldane was fortunate that there were far-sighted civil servants in London who shared his vision, but what would have happened had his ideas on 'regionalisation'— Ashby and Anderson call them a gospel —been fully implemented? Those are ideas which are not yet dead, although they are often advanced by people without vision or Hegelian philosophy —politicians and others seeking to coordinate in order to make education cheaper or "more equal". It would have been interesting had Ashby and Anderson pursued this story a little further, for they do not return to it in their epilogue. Haldane envisaged a system of 'regional' universities—and this involved bringing new universities into existence—each with responsibilities outside higher education as well as in extramural studies.

He never doubted, however, that the universities should "preside benignly" over the regional sub-systems which he called "educational provinces". The "great kind of coordination" of which

he dreamed was not achieved, but if it had been pushed further would it have been under the aegis of the universities? Haldane did not envisage the local authorities as the providers of funds—though he insisted that they should have an initiating and maintaining role in the dynamics of development —but even without funding powers would they have been willing to allow universities "the powers necessary to enable them to organise education from top to toe in their own districts"? How many of them, given expansion of student numbers, would have shared Haldane's view that higher education was "an end in itself"? How many members of his own party shared this view at the time?

Many of the most valuable paragraphs in this book are concerned with aspects of British higher education which do not relate exclusively to Haldane but which have never been very carefully considered in historical perspective. Thus, the sections on the University Grants Committee dispose of some historical misunderstandings and there are new insights into Fisher's Education Act of 1918. What often stands out is the meanness of the Treasury; a few thousand pounds can be argued about inordinately. It is sad to hear Haldane making remarks like "the only effective way of getting the money is by private appeals to very rich men", but it is sadder still to note that, leaving the Treasury on one side, very few rich men indeed showed the slightest interest in responding.

Portrait of Haldane at Work on Education. By Eric Ashby and Mary Anderson. Pp. xvi+202. (Macmillan : London and Basingstoke, November 1974.) £5.95.

To cross linguistic barriers

After Babel: Aspects of Language and Translation. By George Steiner. Pp. viii+507. (Oxford University Press: London, New York and Toronto, January 1975.) £8.00.

ONE strain in the extraordinary logical and philosophical ferment of the Thirties was I. A. Richards' thesis that literature itself had become a proper subject for scientific investigation in that general hypotheses about meaning and interpretation could be tested by the examination of texts. George Steiner's magnificent book should be seen as a survivor from that age of dinosaurs, still very much alive in our own time. To read the book one must actually be interested in literature; it is not enough to be schooled in any of the more recent attempts to handle language in a scientifically acceptable manner, such as Chomskyan linguistics or artificial intelligence.

In Steiner's view, the scientific approach to language has got into the hands of the bad guys, of people who have forgotten what language is actually like. To the extent to which he is right, the book should be compulsory reading for 'language scientists'. He draws attention to the fact that they are usually monolingual (he has been trilingual from an early age) and that little that they have to say is relevant to the real world of spoken and written language because they have a false picture in that they see language simply as a projection of whatever formalism they happen to subscribe to, a formalism that may be quite untrue to the language that comes out of their mouths, just as earlier theorists speculated about phlogiston while their lungs kept them alive by absorbing oxygen.

One might reply that criticism of a scientific activity by appeal to cultural information is absurd: Galileo's opposition, after all, had strong literary evidence for the movement of the Sun. But with language the case is different and, unlike Koestler, Steiner is taking on not established sciences, but would-be sciences like linguistics, philosophy and artificial intelligence; subjects on which Steiner is as much entitled to a hearing as the next man. In particular, he is arguing that anything claiming to be a theory of language must have something interesting to say about translation.

There are three obvious troubles with the way Steiner makes his case: his style of argument, the implausibility of his central thesis about the equivalence of translation and interpretation and the omission of a large issue that scientists would like to see raised (and

---

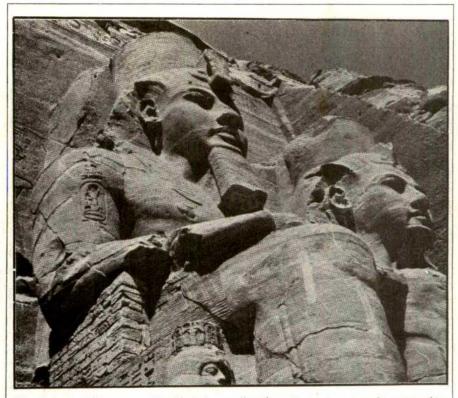
THE brain is a mafs of foft matter, in part of a white colour, and generally ftriated ; in part of a grey or cineritious colour, having no fibrous appearance. It has grand divifions and fubdivifions : and as the forms exift before the folid bone inclofes the brain ; and as the diftinctions of parts are equally obfervable in anmals whofe brain is furrounded with fluid, they evidently are not accidental, but are a confequence of internal ftructure ; or ir other words they have a correfpondence with diftinctions in the ufes of the parts of the brain.

On examining the grand divifions of the brain we are forced to admit that there are four brains. For the brain is divided longitudinally by a deep fiffure ; and the line of diftinction can even be traced where the fides are united in fubftance. Whatever we ob-

serve on one fide has a correfponding part on the other ; and an exact refemblance and fymmetry is preferved in all the lateral divifions of the brain. And fo, if we take the proof of anatomy, we muft admit that as the nerves are double, and the organs of fenfe double, fo is the brain double; and every fenfation conveyed to the brain is conveyed to the two lateral parts ; and the operations performed muft be done in both lateral portions at the fame moment.

I fpeak of the lateral divifions of the brain being diftinct brains combined in function, in order the more ftrongly to mark the diftinction betwixt the anterior and pofterior grand divifions. Betwixt the lateral parts there is a ftrict refemblance in form and fubftance : each principal part is united by tranfverfe tracts of medullary matter ; and

The observations of Charles Bell. From *The Way In and The Way Out.* By Paul F. Cranefield. (Futura: New York, 1974.) $25.00.

almost every other issue one can think of is raised), namely scientific language. I shall look at these in turn.


The central theme is the curse of Babel: the diversity of human languages; and the central thesis of the book is that every act of communication requires an interpretation, and that an interpretation is essentially a translation, whether across a language barrier, across a time barrier (as when we attempt to interpret Shakespeare) or across a barrier between individuals or groups. The book opens with a long speech from *Cymbeline*, and Steiner asks in detail what it means to us now. He turns to other passages in similar detail, ending with Noel Coward, always making the same point: a proper interpretation is hard, even at only 40 years' distance, but with the diligent application of critical method it can be done.

Before I confront his thesis briefly, a digression on the style of the book is essential. Under six chapter headings, Steiner raises an enormous number of issues, sometimes more than one on a page: does language determine our actual perception, as Whorf believed; what was Leibniz's view of a universal syntax and how does it relate to Chomsky's; is women's grammar different from men's; what effect had the statement of the second law of thermodynamics on sensibility and speech at large?

These topics are all raised and dropped during nimble and ebullient leaps from name to name and epigram to epigram: "History is a speech-act, a selective use of the past tense"; "Though the great master Tartakower thought otherwise, we do not ascribe feelings . . . to chess pieces"; "But for all their lively truth, children in the novels of James and Dostoevsky remain in large measure miniature adults. They exhibit the uncanny percipience of the 'aged' infant Christ in Flemish art. Mark Twain's transcriptions of the secret and public idiom of childhood penetrate much farther"; and even, "Sex is a profoundly semantic act".

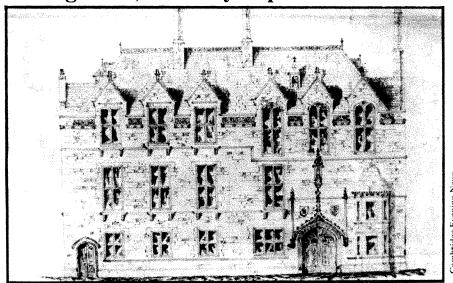
Something intriguing is almost always being said, but it is seldom developed to a point of clarity, or to where the weight of literary evidence, familiar and arcane, that Steiner marshals can tell against his claims and throwaway remarks in any definite way. For there is no time to analyse and discuss in any depth as the whole vast parade of central European scholarship moves on, usually just at the point where one longs for detailed analysis and more examples.

Even what I called the central thesis is not discussed directly in the way it deserves, so let us return to that for a moment. The point of the thesis is to blur the distinction between interpreta-

The Colossi of Ramses at Abu Simbel, guarding the entrance to a temple penetrating 45 metres into solid rock. Possible evidence that the now barren Nubian desert was once comparatively fertile. From *The Ecology of Oases*. By J. L. Cloudsley-Thompson. Pp. vi + 43. (Merrow: Watford, 1974.) £1.25; $4.40.

tion and translation: between the way an individual confronts his own language and the way different languages confront one another. Steiner gives too much weight to what one might call the Telex view of human understanding: that we sit, as it were, in our private offices trying to interpret language coming in from outside. This view makes human communication seem a problem, and is a recrudescence of an old-fashioned empiricism, one that ignores the essentially performative and social nature of language.

If one rejects the 'Telex view' there seems an essential difference between trying to understand what another speaker of your own language is saying, and doing the same for a different language. In the case of interpretation we have the ability to go on asking someone what he means, to form hypotheses, as it were, and test them in discussion. In the case of translation that is exactly what we do not have, and thus the distinctive problems of translation arise. We are, in general, deprived of just that essential "further elucidation" aspect of language.

Steiner's key examples are of interpreting one's language diachronically: he argues that any English of the past is another language, and similarly for the language of women, of the upper classes, and so on. The heart of the matter is the elusive Wittgensteinian notion of a "form of life": in that we can interpret/translate only if we share


an adequately close form of life with those who are the source of the language. One might say dreamily that it is this background knowledge that workers in artificial intelligence are at present trying to formalise and put into their programs.

A large topic presents itself here that it would have been nice to see Steiner discuss: namely, is science such a form of life, and if so can scientific language transcend other cultural boundaries? The question should have come up in the extended discussion of Whorf and his thesis that different cultures have languages describing essentially different worlds. Steiner might well have brought out that Whorf explicitly extended this thesis to scientific language and argued that a psychologist, physiologist and physicist describing, say, the same brain, are speaking different, not mutually translatable, languages and, in that sense, have different cultures. This seems implausible, for we feel that science is a uniform international culture and language. And yet, had Steiner found room for this topic he would almost certainly have drawn our attention to modern Chinese scientific journals, particularly medical ones, where it is not at all clear that they can be understood outside the Maoist frame of thought.

It is a highly personal, stimulating and infuriating work but, warts and all, a considerable achievement.

Yorick Wilks

Solid ground, Himalayan peaks

The Cavendish Laboratory, 1874–1974. By J. G. Crowther. Pp. xvi+464. (Macmillan: London and Basingstoke, October 1974.) £25.00.

THE foundation of the Cavendish Laboratory a century ago was the greatest single consequence of the mid-Victorian movement to advance the cause of science in Britain. During the preceding two centuries the development of science in the English universities had been paralysed by the Clarendon Code which, as G. M. Trevelyan said, subjected them to "the bondage of Church monopoly" so that only professing Anglicans could teach and study there. Most science in England was therefore found outside the universities—in the Lunar Society at Birmingham, or the Literary and Philosophical Society at Manchester, or the Royal Institution—a fact from which Cardinal Newman ingeniously argued that experience had shown that for its own well-being science should be pursued outside universities rather than within them. Only in Scotland, where the Clarendon Code had been repealed following the 1688 Revolution was it possible for non-Anglicans and free thinkers to go to university—a fact which contributed much to the eminence of Scottish science, philosophy, and economics in the century and a half before 1871, when at last the University Test Act abolished religious discrimination in England.

In the same year James Clerk Maxwell was appointed as the first Professor of Experimental Physics in Cambridge. The university had procrastinated for some years over the creation of the Chair and its associated laboratory, having been influenced by such remarkable arguments as "A Prussian is a Prussian and an Englishman an Englishman and God forbid that it

should be otherwise" by the Master of Sidney Sussex. What finally moved the university was the offer (which was accepted) by its Chancellor, the Duke of Devonshire, to cover the cost of building the laboratory and of buying its equipment.

In this history, Mr Crowther sets the foundation of the laboratory in perspective, and takes us through its continuously happy fortunes ever since. No Chair in the world has had such a distinguished and creative a succession of holders, and Mr Crowther provides many sidelights on their personalities. We find Maxwell, for example, working in his shirtsleeves with each hand in a basin of water to compare the strengths of electric currents, and exclaiming "each man his own galvanometer!" by way of explanation to an American visitor, S. P. Langley (of the bolometer and flying machine), who had been brought unexpectedly by Schuster to be introduced.

Maxwell at the time was confirming the experiments of Henry Cavendish, whose papers he edited in what Mr Crowther describes as "the finest contribution to the history of science in the English language". Maxwell had a strong historical sense but Mr Crowther makes the general point that "The Cavendish, like the whole of British science, was sublimely disinterested in its historical aspects. Why British science should have been so non-historical is a significant question". Perhaps it is a sign of exhilarating progress to have so much to do and think about in the present and the future that effort in attending to the past, or even preserving the present for the future, is grudged. But it has resulted in a cleavage in Britain between practising scientists and those who style themselves "professional historians of science" that too few of us are trying

to repair, and it is a pleasure to acknowledge Mr Crowther's splendid efforts over many years in this direction.

Among the many illuminating comments that he has gathered from past and present Cavendish members there is one that—if it really means what it says—is mildly surprising: "Some consider that the Cambridge undergraduate . . . has done more for Cavendish science than the talented research students coming from outside. They produced a large body of very good scientists of the second level, which provided an excellent support for the front rank of genius". Such a comment must have overlooked the fact that J. J. Thomson, Rutherford, Chadwick, Aston, C. T. R. Wilson, Cockcroft, Ryle, and Crick were all undergraduates elsewhere; and Maxwell took his first degree at Edinburgh.

Besides its value as straightforward history there is much to be dug out of the book by anyone interested in the problems of running a laboratory and of seeing it through from one phase of success to another. There is, for example, the principle that Bragg took over from military organisation that one man cannot effectively keep contact with more than six subordinates on a day-to-day basis, which led to the organisation of the large laboratory into groups which in turn may have again to be sub-divided. And those who press for the centralisation of university services such as workshops might be reminded of the experience that, even inside a single laboratory such as the Cavendish, "It was much more economical to do as much as possible in a small workshop belonging to a group rather than in a central workshop". And again there is Bragg's estimate that Britain produced one good physicist a year per million inhabitants—a sobering reflection on the optimism of the Robbins expansion.

The one truly unfortunate thing about the book is its price—£25.00 after the publishers had already advertised it at the prohibitive price of £14.00. And especially in view of the price the quality of the photographic reproductions is poor. For neither of these defects is Mr Crowther responsible, and it is much to be hoped that somehow the story which he tells will be made much more widely available than the present price allows. For the story is magnificent: Maxwell and Rayleigh setting the foundations; J.J. discovering the electron (when the total bill for 1896 was £1,067 7s 0d plus his own salary and another £420 for the salaries of university lecturers and demonstrators); C.T.R. inventing the Wilson Chamber; Aston finding the mass defect and thereby the clue to nuclear energy; Cockcroft and

Walton transmuting lithium with protons; Chadwick finding the neutron; Blackett recognising the positive electron; Crick and Watson elucidating the structure of DNA; Josephson predicting his effect; Hewish and Jocelyn Bell finding pulsars. Besides this Himalayan chain of peaks of discovery in the Cavendish itself there have been major discoveries by Cavendish men working elsewhere—for example, the wave nature of the electron by G. P. Thomson or the π-meson by C. F. Powell. But the Cavendish story is not just of these peaks; there has been an enormous amount of supporting work over a wide range of physics, and from the Cavendish many physicists have gone outside to other universities, to the schools, to industry, and to government establishments.

So many achievements could induce complacency; but so long as the Laboratory maintains the spirit of Professor Pippard's 'The Cavendish Tradition' (*Nature*, **249**, 602–603; 1974) it need have no fear that "Nothing fails like success".   **R. V. Jones**

Scientists only human in their quest

Originality and Competition in Science: A Study of the British High Eenergy Physics Community. By Jerry Gaston. Pp. xix+210. (University of Chicago Press: Chicago and London, 1974.) £5.50.

GASTON'S sociological study of the British high energy physics (HEP) community is most interesting. Knowledge in the natural sciences with all its fallibilities is less uncertain and less subjective than knowledge in the social sciences or the humanities. The corollary has, too often, been a belief that natural scientists conduct their scholarly inquiry in a more rarefied way than other people and are indeed rather more rarefied people. This belief has been encouraged by the historians and philosophers of science and sociologists have added their norms. Dr Gaston quotes four norms or rules which Robert Merton ascribes to scientific activity: organised scepticism, universalism, communality and disin-

terestedness. Each norm is not unique to science but together they are said to be peculiar to the ethos of modern science. American sociologists of science, led by Merton himself and by scholars such as Hagstrom have, however, shown how often scientific activity diverges from those norms.

Dr Gaston looks at some of the norms in relation to the British HEP community at one point in time—1967–68. One of the advantages of his study is that its coverage is almost complete and does not rely on small samples: about 220 scientists were located at 23 different universities or government establishments, of whom 203 provided information and were interviewed.

The author has analysed their social, educational and professional background; the kinds of research they conducted; their contributions to the scientific community—that is, their productivity; the recognition they received from the scientific community; their attitudes towards research; the prevalence and severity of competition; and their communicative behaviour. Throughout the book, in pursuing these themes, Gaston distinguishes between the views and habits of theoretical and experimental physicists.

He also makes valuable comparisons with the studies of American scientific communities. It is, however, unfortunate that he follows too closely the pathways set by his predecessors so that some of the problems which are especially interesting in HEP are omitted. Thus, he omits the scientists who operate accelerators and other machines "because they are more akin to engineers than scientists". He does not mention the machine builders at all, but it is wrong to dismiss the machine-providers whose performance in terms of sheer physics alone has been so great. The relationship between them and the machine-users is important in the study of any HEP community. Again, in high energy physics, the identity of the individual scientist has increasingly been lost within team identity. Much more attention needs to be given to the effects of this change in the property system of science upon motivation and relationships.

These qualifications apart, Gaston produces 45 statistical tables which reveal fascinating positive or negative correlations. For example, why are high energy physicists significantly more productive at some institutions than at others? How is the number of publications related to prestige of the university at which the PhD was gained, prestige of present affiliation,

---

The Ciba Foundation: An Analytic History, 1949–1974. By F. Peter Woodford. Pp. viii+212+8 plates. (Associated Scientific : Amsterdam, Oxford and New York, 1974.) Dfl. 38; $14.75.

THE decision of the Ciba Foundation to commission an analytical history of its first 25 years has turned out to be a wise venture. The analysis, undertaken by Dr Peter Woodford, has been carefully performed and, through his avowed aim to be critical, he has managed to bring out a number of points of importance. The Ciba Foundation with its symposia and publications is so well known that it is in danger of moving beyond the range of criticism. It is, therefore, of importance to analyse the secret of its success and to try and separate the method from the qualities of those who run it. Inevitably, that is an impossible task.

The Ciba Foundation is a product of the knowledge, experience and attitudes of Dr Gordon Wolstenholme and his able colleagues. The fact that their purpose and method of working was timely and has filled a special place in the world of medical research is a further tribute. Maybe all our institutions are a product of individual effort at a special time. Certainly, it is always very difficult for any successor to take over and continue where his predecessor left off and this will be equally true of the Ciba Foundation because of the unique, accumulated interpersonal relationships developed by its staff.

The importance of this book lies, therefore, in its analysis of those features of the foundation that may be greater than its leaders. The analysis of the reasoning which led to the decisions on the size and nature of the meetings in general and also for more specific topics is thus the most important aspect of the book.

It is also important that a study has been made of the impact on medical research of the activities of the foundation. This has proved to be a difficult task which has daunted many who have previously attempted it in other organisations. Sufficient to say that the record of the Ciba illustrates the flow of progress that can develop from bringing toegther, in relaxed surroundings, people from different disciplines and nations so that they may stop for a while to contemplate matter that are set on one side in the busy working day. The Ciba Foundation has achieved its aim and provides the ideal illustration of the importance of having specialised activities supported by private funds. It also shows that it is not size, but quality, that counts.

I can make only one factual criticism. It is not correct to say (page 4), "The essence of the law (Charities Act) is that those who provide the money disposed of by the trust may not be represented on its governing body". This book will be of interest to all those who know and admire the Ciba Foundation through its books or meetings. It is a worthy tribute to the singleness of purpose of Gordon Wolstenholme.   **P. O. Williams**

proportion of time spent on research, number of hours spent weekly on research, proportion of time spent on teaching, class of undergraduate degree, chronological age, professional age? What is the relationship between recognition and these variables and what is the relationship between productivity and recognition? Competition is measured by the number of times scientists have been anticipated through having research findings similar to their own published first by someone else. What anticipation have British HEP workers experienced, for example in relation to their rank or by comparison with American scientists? Having been anticipated, did they publish or not publish? As for communication, what is the most important method of obtaining information relevant to research, by type of HEP, rank, professional age?

How does verbal communication work and which are the most important journals?

Equally, if not more, illuminating are the extracts from transcripts of conversations about competition. One suggestion is that competition helps to motivate scientists who otherwise might put forward less than their best effort. An experimentalist is quoted as saying, "I have suspicions that less than one physicist in three that I've met is really and deeply and drastically motivated by a desire to 'find out' ". There is much material in this book to show just how cut-throat the competition can become —both between individuals and between continents—together with material which suggests why American physicists 'beat' European physicists in certain races of discovery. Gaston records his evidence about the "three main

methods of deviance" which scientists sometimes use to get the recognition which eludes them: hasty publication; fraud and theft; and secrecy.

In his conclusions, the author does not ask squarely where his own evidence leaves Merton's four rules of science. He finds that the reward system in British HEP communities, unlike the system in America, operates in a universalistic fashion. Recognition is highly related to productivity and theorists receive more recognition than experimentalists. But affiliation with a particular type of university or a department in a particular prestige category has no effect on opportunities for scientific recognition. The four rules are, however, meant to hang together and Gaston shows that scientists are indeed human in their quest.

Margaret Gowing

The Competent Infant: Research and Commentary. Edited by Joseph L. Stone, Henrietta T. Smith and Lois B. Murphy. Pp. viii + 1,314. (Tavistock : London, 1974.) £11.00.

MOST books consisting of collections of published papers are worth neither reviewing, buying nor reading: the present volume is an exception. The editors have done a remarkable job of arranging the selected papers in logical order, shortening them, and with the help of their own commentaries producing a coherent book. There are two further reasons why this collection is particularly useful. First, infant development is a topic on which spectacular progress has recently been made and second, as there are few journals devoted specifically to it, papers on the subject have appeared in such a wide range of journals that no one person could possibly scan them all: in *The Competent Infant*, we find papers from the *Journal of Ophthalmology* rubbing shoulders with extracts from *Psychosomatic Medicine, Vita Humana,* and *Cognitive Psychology.*

The book demonstrates the ways in which our ideas about the competence of infants have been revised drastically by the work of such pioneers as Wolff, Escalona and Prechtl. Until some 20 years ago, it was widely accepted that new-born babies were almost entirely passive and incapable of anything much in the way of organised adaptive behaviour. More recent research shows quite the contrary and the watershed may be placed at the publication of Wolff's now classic paper in 1959. He found that, if you catch your infant at the right moment, it will emit highly organised and complex behaviour. As Prechtl puts it: "If you put a new-born infant baby in a supine position

in its cot and cover it with a blanket up to the neck, of course it gives the impression of being a kind of vegetable which just cries and sucks from time to time and that's all". What Wolff discovered was that the reactivity of the new born depends on its state. He classified such states into sleep (regular, periodic and irregular), drowsiness, alert acvtivity and alert inactivity. It is only when the infant is alert and

---

More than vegetables

inactive that it will attend to outside stimuli; when it is alert and active, crying or threshing around, it pays little attention to external stimuli, particularly to new stimuli. During the first week of life, the infant spends only about 10% of the day time in alert inactivity. In this state "his respirations are regular . . . his eyes are wide open, shiny and capable of conjugate eye movements, and he makes visual and auditory pursuit movements . . . the skin is pink but not flushed". Such

behaviour tends to occur immediately after the baby has satisfied its physiological needs such as feeding and defecating. Experimenters patient enough to wait for such periods have been rewarded by observing complex behaviour even on the first day of life: some infants in fact show about an hour of alert inactivity starting 15 minutes after birth.

Recent research, stemming from Wolff's insights, has shown that there is considerable innate organisation of perceptual and motor functions. One of the most remarkable experiments republished in the present book is Sackett's ingenious demonstration that monkeys have an innate capacity to recognise not merely other monkeys but whether or not the other monkey is in a threat posture; this work is now nearly 10 years old and its implications are so important that it is very regrettable that, as far as I know, there have been no independent attempts to replicate it. There is also ample evidence that personality traits which tend to remain constant throughout life may appear in new-born infants: American babies of Chinese origin show less irritability and impatience than do whites born on the same ward and tested within a few hours of birth.

The book should give pause to those who think either that psychologists rarely discover anything we did not know already or that introspection and every day experiece are all we need use to infer the structure of the mind— a belief that has recently been resuscitated by some polemicists for the new branch of technology known as 'artificial intelligence'.

The book is 1,300 pages long and nicely produced: at £11.00 it surely rates as a best buy. **N. S. Sutherland**

More behaviourism

About Behaviourism. By B. F. Skinner. Pp. 256+viii. (Jonathan Cape: London, February 1975.) £3.50.

PROFESSOR Skinner is unrepentant. Assailed by the liberal and radical establishment as a reactionary witch-doctor intent on subjecting human freedom to blind conditioning, attacked by the new school of linguistics and cognitive epistemology as an ignorant primitivist, Skinner not only maintains his position but makes it more dogmatic.

The concept of mind is an obscurantist 'invention' largely attributable to Plato. The only distinctive characteristic of verbal behaviour is the fact that "it is reinforced by its effects on people". Dreams, fantasies, *déjà-vu* are merely re-cognitions of "what we have once cognised", in some of which certain controlling features of self-knowledge are defective. Human thought equals human behaviour: *sum ergo cogito*. Faith is just "a matter of the strength of behaviour resulting from contingencies which have not been analysed". Mentalist explanations "explain nothing". Behaviourism, on the contrary, puts us in a position to alter and improve the condition of mankind if only we will apply its commanding insights into the role of the environment and into the agency of such cardinal notions as reinforcement and operant behaviour.

Neither the strategy of the argument nor the tone of mildly outraged common sense are at all new. If there is innovation it can be found in the tactics of Professor Skinner's case, particularly in his increasing resort to a Darwinian idiom. In an important sense, we are told, "all behaviour is inherited, since the organism that behaves is the product of natural selection. Operant conditioning is as much a part of the genetic endowment as digestion or gestation". The origin of behaviour "is not unlike the origin of species. New combinations of stimuli appear in new settings, and responses which describe them may never have been made by the speaker before, or heard or read by him in the speech of others. There are many behavioural processes generating 'mutations', which are then subject to the selective action of contingencies of reinforcement."

What is going on here is plain. Darwinian and post-Darwinian terminology is being used in an attempt to refute the drastic onslaught on behaviourism by Chomsky (whom Skinner, either in coyness or contempt refuses even to mention by name). Dismissing the entire basis of innateness in transformational–generative theories of speech and consciousness, Skinner declares that "grammatical behaviour" has always been shaped by the reinforcing practices of given verbal communities in which some behaviours were more effective, more provocative of useful response, than others. Sentences are not generated by imaginary 'deep structures' but, like all other human proceedings, by "the joint action of past reinforcements and current settings".

As one follows this controversy, a sense of exasperation mounts. It is so utterly clear that both sides simplify, distort, and finally trivialise reality. Skinner is perfectly right when he observes that Chomsky's model is full of logical and evidential loopholes, that it absurdly neglects environmental-historical factors, that it is dogmatic and even 'mystical' in its presupposition of deep structures and mental 'presettings'. Chomsky, on the other hand, has shown beyond doubt that a stimulus–response paradigm along Skinnerian lines is totally inadequate to explain either the process of language acquisition and innovation or the prevalence (or what looks like the prevalence) of rule-governed similarities across the field of all known grammars. But, surely, there is no need here of a doctrinal either/or. The evolution of human speech and cognition is neither Skinnerian nor Chomskyan, but represents a constant dynamic reciprocity between universal neurophysiological features on the one hand and the contingencies of the environment on the other, between predisposition and reinforcement, between mimesis and discovery. Indeed, using a Darwinian analogue, one would want to argue, with far more attention to the facts than is shown by either behaviourism or transformational–generative linguistics, that man's language capacity is uniquely adaptive. Through words he constructs worlds more bearable than that of his organic surrounding. Through the future tense he does something to circumvent the totality of biological death.

Skinner's contributions to experimental psychology, to learning theory and the understanding of conditioning and reinforcements stand secure. It is a pity that they should be overshadowed by an embattled dogmatism the political add philosophical consequences of which are not necessarily sinister, but are certainly naive.   **George Steiner**

Animal Nature and Human Nature. By W. H. Thorpe. Pp. xviii+435. (Methuen: London, January 1975.) £7.20.

IT is of interest to compare *Animal Nature and Human Nature* with Skinner's new book, *About Behaviourism*. Although Thorpe thinks human behaviour cannot be explained solely by genetic and experiental factors whereas Skinner adopts a strictly deterministic position, the similarities between the two books are more striking than the differences. Both authors believe that if human behaviour were so determined, our freedom of will would be constrained; both rely heavily on assertion and on appeals to authority rather than on argument, though naturally the quoted authorities differ; both dogmatically reject computer programs as possible models of the mind without examining any such programs; both put forward Utopian views of man's future without taking the trouble to think out what sort of Utopia they want; neither gives evidence of having read, let alone

All slots open, flaps down, and undercarriage lowered, the barn owl approaches home. From *Natural History Photography.* Edited by D. M. Turner Ettlinger. Pp. xxvii+395. (Academic: London, 1974.) £8.80; $23.25.

understood, any arguments against their own position; finally, nothing of any scientific or ethical consequence follows from the contrasting stances taken up by each author.

Thorpe's book is perhaps the less bad, if only because, unlike Skinner, he gives some interesting examples of the results of his own science. He culls from recent work in ethology instances of fixed action patterns, animal communication systems, and social organisation in mammals. Such phenomena have an inherent fascination: like most ethologists Thorpe is at his best when describing such behaviour and speculating on its survival value. He is less good at specifying the mechanisms that mediate it. On many issues, such as nature against nurture, he takes a sensible position—he rightly castigates Hebb for his declaration that it is absurd to ask how far a given piece of behaviour is innate, how far it is learned. Thorpe's chapter on perception is weak: he still thinks of perception in terms of pattern recognition and fails to get across the idea that perception must involve forming rerpesentations of the outside world which can be manipulated in ways that serve to guide the organism around. In this chapter, his accounts of much experimental work are somewhat cursory and inaccurate.

In arguing for an antireductionist, emergent view of mind he fields the standard team of obscurantists: Koestler, Polyani, McKay, Eccles, Dobzhansky, Weiss, Hardy and Teilhard de Chardin. His eleven is made up by enrolling two new players, Chomsky and Popper, and by using a theologian (Hick) as long-stop. With the exception of the two beginners, these players proceed to throw around terms like 'emergent', 'consciousness', 'determined', 'free-will', 'wholes-greater-than-the-sum-of-their-parts', and so on. We are treated to such sentences as "the ego's view of the physical world will thus be mediated by a mechanism working just like television". On page 341 there is even a diagram showing (with a dotted line) how "mental space" intersects three-dimensional physical space. The players have such an enjoyable time tossing the ball to one another and cheering each other on, that they seem quite to have forgotten to notice the opposition. Nevertheless, they make their opponents' task very difficult, since the game is played with no rules or definitions; but it may be worth examining a few of the many *non sequiturs.*

Thorpe accepts McKay's proof that behaviour is indeterminate: in attempting to predict our own behaviour, we change our internal state and, short of an infinite regress, we cannot take such changes into account in making our

predictions. The premise is correct but the conclusion does not follow: do we regard computers as being indeferminate because no program could completely predict what it will do? Again, it is correctly stated, following Popper, that at each level of explanation it is necessary to evolve concepts appropriate to that level. To explain and predict the behaviour of a gas we need concepts like pressure, appropriate to collections of molecules not to individual molecules, and to explain the workings of a computer program we need concepts such as 'conditional jump', 'recursion', and 'iterative loop' that cannot be applied to transistors. If this is all Thorpe means by "emergent qualities", then we can readily concede that a system with the highly unusual organisation of the brain is likely to have emergent qualities, without committing ourselves to the belief that there is some special sense in which human behaviour is 'undetermined' and without supposing that there is a two-way interaction between consciousness and matter. Thorpe also uses the "gawping at Nature" argument: we do not understand why some bird songs and displays should be as elaborate as they are, but present ignorance is no reason for assuming that no scientific explanation will in future be found. It is particularly curious that Thorpe should use this argument since else-

where he points out that some highly complex behaviour once thought to indicate the presence of a life-force or creator can nowadays be explained in mechanistic terms.

The asertion that "Sir Karl Popper comes down with all the weight of his great learning and experience heavily on the side of dualism" surely does not exempt Thorpe from considering the difficulties inherent in this position. The polemical parts of the book are written in the vaguest of terms. Thorpe dismisses computers as models of the mind without discussing any work in artificial intelligence, yet telepathy and clairvoyance are uncritically accepted on the strength of the questionable work of such experimenters as Soal and of Koestler's collection of unlikely coincidences. The distinguishing characteristic of the human race is said to be religion.

The book is based on a series of Gifford lectures delivered at St Andrews: such lecturers are instructed, under Lord Gifford's will, to deal with natural religion "as a strictly natural science, the greatest of all sciences"; but this instruction is usually interpreted by the lecturers themselves to mean they should treat of their own subject matter in religious terms. The present book is a fine example of the Gifford Lectureship Syndrome.

Factors leading to schizophrenia

Genetics, Environment and Psychopathology. (North Holland Research Series on Early Detection and Prevention of Behaviour Disorders, vol. 1.) Edited by S. A. Mednick, F. Schulsinger, J. Higgins and B. Bell. Pp. xiv + 346. (North Holland: Amsterdam and Oxford; American Elsevier: New York, 1974.) £9.25.

IN 1962 the Psykologisk Institut in Copenhagen began a research project aimed at the early detection and prevention of mental illness. This book brings together a number of studies conducted at the Institute over the last 10 years. Many have contributed to the research, and 20 authors from the USA, Denmark, Iran and the UK, write in this volume.

The authors were dissatisfied with research on people already schizophrenic and so they conducted prospective studies of people at risk. They used children of schizophrenic parents and selected control groups. Unexpectedly, they found that perinatal factors influenced later outcome and so they established a new study in greater detail, using babies born in Copenhagen between 1959 and 1961. They linked that with Professor Preben Plum's detailed peri-

natal study of 9,006 deliveries during that period.

The methods that were used are described fully. They were of a high standard and good contact was maintained with family doctors and hospitals. There is a full list of references which will be valuable to others studying in this field, and there is an index.

The book represents a considerable advance towards the unravelling of genetic and environmental factors in the origins of schizophrenia. Electrodermal responses were used in several of the studies, and some of the authors characterise schizophrenia as a learned pattern of avoidance responses. As treatment seems to offer little, attention has been concentrated on methods of prevention of the development of schizophrenia in 'high risk' children. The authors have made excellent use of the Danish Register of Adopted Children. Schizophrenia is only one of the mental illnesses studied, and the effect on being reared by a schizophrenic mother is tentatively separated from inherited factors.

This volume is good value for money for all research workers in this field and will be of great interest to all field workers. **R. Mac Keith**

Evolution of sex

THIS is an important and infuriating book*. It is important because it is a scholarly and sustained attack on the most important problems in evolutionary biology; the evolution of genetic mechanisms, of sexual dimorphism and of society. It is infuriating because it fails, narrowly but decisively, to provide the illumination promised by the first two chapters.

The problem which Ghiselin sets out to cover is more easily stated than solved. In Darwin's theory of natural selection we have an explanation of evolution in terms of the success or failure of individuals to survive and leave descendants. As an explanation of characteristics which promote individual survival and reproduction, this is fully satisfactory. But sex and genetic recombination are often interpreted in terms of their contribution to the survival of the species and not of the individual, and social behaviour in terms of the survival of the community. How is the evolution of such characteristics to be explained? Two positions seem possible. The first, the "group selection" explanation, is to argue that selection between species (that is, the survival and division of some species and the extinction of others) produces genetic mechanisms adapted to ensure species survival. The second, strongly espoused by Ghiselin, is that sexual adaptations evolve because of the advantages they give to the survival and reproduction of individuals—that is, by natural selection in Darwin's sense.

Ghiselin has qualities which adapt him for tackling these questions. His philosophical position is sound (that is, I agree with it); he distrusts teleological explanation, despises Baconian induction, and regards holism as an illegitimate attempt to smuggle teleology back into biology. He has a sensitive nose for Panglossianism, which can be defined as the belief that the characteristics of organisms exist to ensure the survival of species and of ecological communities. Although accusations of Panglossianism are usually indignantly denied, such views are widespread among evolutionists, ecologists and ethologists, as Ghiselin makes clear. Equally important, he has the widespread knowledge of natural history which is needed to test evolutionary hypotheses.

Why then does he fail? Ultimately, because he does not think as a geneticist, and because he abjures mathematical language. He rightly remarks that if a mathematical model fails to

*The Economy of Nature and the Evolution of Sex. By Michael T. Ghiselin. Pp. xii+346. (University of California: Berkeley, Los Angeles and London, December 1974.) $12.05; £7.10.

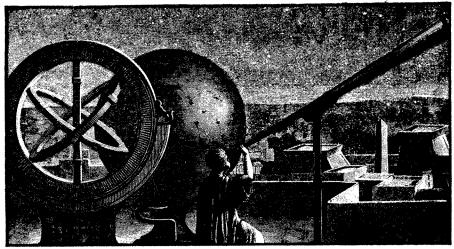
Understanding Homosexuality: Its Biological and Psychological Bases. Edited by J. A. Loraine. Pp. 217. (Medical and Technical Publishing: Lancaster, October 1974.) £6.50.

HOMOSEXUAL behaviour is of major interest both scientifically—because of the general problems of the sources of sexual preference, gender identity and gender behaviour—and socially, because of the legal, occupational and other disadvantages suffered by those whose preference is homosexual. Three of the chapters in this book fall under the scientific heading and five under the social heading; the remaining chapter is concerned with venereal disease and homosexuality.

Two of the scientific chapters are reviews, one mainly on males, by Cooper, and one solely on females, by Kenyon. Both are reasonably adequate on the biological sources of homosexual behaviour—Kenyon particularly so—and on parent–child relationships, but neither pays more than passing attention to the potential contribution of the psychology of learning to the acquisition and maintenance of homosexual behaviour. Classical and instrumental paradigms and direct as well as modelled experiences are likely to be relevant—as they are for all kinds of behaviour. Freund *et al.* report an interesting series of experiments which sought, but did not find, evidence for bisexuality of response. In all three scientific chapters almost all reported studies compared heterosexuals with undifferentiated homosexuals, rather than using the heuristically more useful division into primary (life long) and secondary (non life long) homosexuals.

The remaining chapters are concerned with the legal, theological, and general social responses of the heterosexual majority to the homosexual minority. Grey contributes a particularly thoughtful, sane and eloquent plea for the equality of status of all sexual variations involving consenting partners, both as objects of scientific study and in terms of social esteem. Ramsay and others describe the rapid progress towards equal status in Holland. A final chapter, on the status of the homosexual, by Chew *et al.*, skims rapidly over both social and scientific aspects and includes the provocative assertion that heterosexuality is the "primary cause" of the "dilemma of overpopulation".   **Philip Feldman**

---

predict the nature of reality, it is the model which must be changed. But models do make clearer what is being assumed (even if tacit or unconscious assumptions are made, as is often the case, a careful examination of the model will usually reveal them), and they show more certainly whether the conclusions follow from the assumptions. Ghiselin seems to me to fall down on both these points. For example, on page 69 he offers an explanation for the association between diploidy and complex multicellular structure. I simply cannot form a clear picture of the genetic and selective mechanisms being proposed.


On the still more crucial point of the short-term individual advantage of sex, my difficulty is different. I do understand, in a very vague way it is true, what is being proposed. The snag is that I am familiar with several attempts to make these proposals more precise. It turns out that the conclusion—an immediate advantage for sex—seems to follow only if one makes rather extreme and implausible assumptions. Ghiselin would presumably retort: so much the worse for the model. Oddly enough, I agree with him. Plausible models giving an individual advantage to sex may well be possible; Williams and Mitton have made a promising start. But it simply does not do to ignore the difficulty and to appeal to nature as a witness. If we do not have a clearly formulated theory we do not know which facts support it.

Ghiselin's reluctance to think genetically lets him down in other contexts—for example, in his discussions of the role of kin selection in the evolution of societies, and of Fisher's idea of a positive feedback on female choice in sexual selection (it is uncharacteristic that he does not ascribe that idea to Fisher; one of his virtues is his respect for history). Thus, he seems to regard kin selection as a needless complication, only to be invoked if nothing else will do. I would argue that it is a process which is bound to operate whenever relatives live close to one another, and which therefore must be considered in any discussion of the evolution of societies. I suspect Ghiselin would dismiss this as *a priorism*; in fact, I am asserting that if we accept the (empirically tested) theories of genetics, then certain things follow, among them Fisher's and Hamilton's arguments. Of course, the relative importance of these and other processes have to be investigated in particular cases.

There is much in the book that is stimulating and illuminating, particularly in the discussion of sexual selection. But in some ways Ghiselin invites an ungenerous review. He is curiously dismissive of other people's ideas, with the exception of Darwin's. It is true that Panglossianism is rife, but it is not universal. Other evolutionists have been attempting non-teleological explanations of these phenomena. Ghiselin may have more allies than he thinks.   **J. Maynard Smith**

Covering the Universe

Astrophysics of Gaseous Nebulae. By Donald E. Osterbrock. Pp. xiv+251. (Freeman : San Francisco and Reading, January 1975.) £8.90.

IN the Milky Way and in other galaxies the very brightest stars are generally surrounded by masses of bright interstellar gas. These are the H II regions, so called because the hydrogen there is in the form of H^+. Other atomic species, notably helium, are also largely ionised as well.

All of these ions are continually recombining with the electrons present. If recombination takes place to an excited state then the resultant downward cascade of the recombined atom or ion produces a rich spectrum of emission lines. The optical observation of H II regions relies on these lines; the radio observer can also detect spectral lines arising from transitions between very high levels of the atom concerned. H II regions show up in the radio continuum as well. The emission process here is free–free emission by an electron in the field of an ion.

In principle, the observations contain an enormous wealth of information about the density, temperature, and composition of the gas in H II regions, and its distribution in space. But to tap this wealth requires a considerable amount of physical analysis. Much of the required work has been done by Don Osterbrock and his colleagues; in this book he presents an account of the subject which is so good that it should be unnecessary from now on to consult any earlier work.

The processes by which an equilibrium is attained in a diffuse mass of gas sitting around a bright star which is rich in ultraviolet radiation include radiative transfer and electron collision processes; since many different types of atom are involved the situation becomes quite complicated, but the author never lets it get out of hand. For good measure he also deals with planetary nebulae, where many of the same phenomena occur on a smaller scale.

But there have been many developments in our understanding of H II regions since the text was completed (about three years ago) and in particular much attention is now being focused on compact H II regions. These are objects whose linear dimensions are smaller. They are often heavily obscured by dust, and are therefore observed mainly at radio and infrared wavelengths. There is a definite association between dense molecular clouds and these compact objects. Very probably they occur in regions where star formation is still active, and the stars involved in them must be among the youngest objects in the sky. Some of these developments are hinted at in the book, but I hope that Professor Osterbrock will be persuaded to write a second, more detailed, volume to deal with these more recent discoveries.

F. D. Kahn

Interstellar Communication: Scientific Perspectives. By Cyril Ponnamperuma and A. G. W. Cameron. Pp. 226. (Houghton Mifflin: Boston, 1974.) £3.50.

ONLY two serious possibilities exist for acquiring information about extraterrestrial life. The first is by direct rocket flight within the Solar System. It is possible, though by no means sure, that one of our sister planets may possess a primitive biosphere. The second is by interstellar communication with remote technical communities elsewhere in the Galaxy. With the declining interest in the spaceflight programme, the exciting if somewhat exotic, possibility of radio communication with extraterrestrial civilisations is achieving mounting respectability and being given serious consideration by astronomers, biochemists, physicists and even social scientists.

In the summer of 1970 a conference took place at NASA's Ames Research Center to bring together acknowledged experts on this nascent subject. The presentations at that conference have now been made available in this book. Enthusiasts will recognise the names of the contributors—Sagan, Drake, Bracewell, Arbib, McCarthy, Aranoff, Oliver and Morrison, as well as those of the editors, Ponnamperuma and Cameron. The book is a well-balanced and eminently readable account of all the varying aspects of this intriguing and daring topic. Although this work constitutes a serious and in-depth study, including technical material of interest to experimentalists, the informal style and interdisciplinary profile of the subject matter will command a wide readership from non-specialists of many disciplines. (It also contains a 39 page bibliography.)

The feasibility of radio communication with extraterrestrial civilisations depends heavily on the proportion of stars in the Galaxy which are likely to support life-bearing planets with technical communities capable of transmitting, receiving and interpreting radio signals. Surprisingly, the most uncertain parameter which determines this proportion turns out to be a social one— the mean lifetime of technical communities. The contributors apparently share a strong opinion that the physical and biological conditions necessary for the formation of life are extremely common throughout the Universe and that given the appropriate type of star, intelligent life of some sort is almost inevitable. Carl Sagan comes up with a formula which predicts that the number of technical communities in the Galaxy is 10% of their mean lifetime in years. This implies the curious result that either the Galaxy is teeming with intelligent life, or, if our civilisation is typical, we are already doomed.

With the optimistic assumption that the technical phase lasts billions of years (there is plenty of time available since the Galaxy was formed) then there may be a few hundred million communicative planets around us.

The formidable problem which then emerges is where to look. Even the optimistic estimates indicate the necessity for a search pattern covering thousands of stars out to a distance of perhaps 1,000 light years—a daunting prospect. Nevertheless, in the early 1960s Frank Drake monitored two nearby stars at 21 cm wavelength in the famous Project Ozma, in the hope of detecting intelligently directed signals. A vastly more ambitious programme is

proposed by Bernard Oliver, arising from a careful study which culminated in Project Cyclops, a summer study at Ames in 1971 This project involves the proposal for the construction of a huge array of 100-m radio dishes spread out over about 100 km², to search a million stars out about 1,000 light years away This search might take many years to complete, but in view of the cosmic importance of the project, such a long term allocation of resources is deemed to be justified Oliver devotes part of his paper to the discussion of concrete proposals for hardware and experimental procedures The system could also be used for transmitting, but in view of the fact that we must be by far the youngest technical community in the Galaxy, it is assumed that the responsibility for this rests on other (extra-terrestrial) shoulders

Some lively discussion is presented about how two communities who know that they want to contact each other but don't know where to look ought to go about attracting attention Simple radio beacons are an obvious if rather unsubtle procedure Dumping a rare

metal into the local star to bewilder distant spectroscopists is another suggestion Bracewell discusses an intriguing conjecture that probes may be sent around the Galaxy to lie in wait near a hopeful system If radio signals are received it immediately beams them back as a delayed echo, thereby attracting the attention of an assured audience Novelties of this sort, though purely speculative, are nevertheless of great general interest and this book is to be thoroughly recommended as a good all-round introduction to the subject

One final point Most of the contributors reject the possibility of direct spaceflight between galactic communities because of the vast distances and uncertain destinations involved It is difficult to fault their reasoning Anybody who is uneasy about signalling other, possibly bellicose, intelligent beings need fear no invasion In any case, even Marconi's pioneering signals are now a mere few dozen light years out in space and very probably haven't yet reached any interested ears

P. C W. Davies

Action at a Distance in Physics and Cosmology By F Hoyle and J V Narlikar Pp x+266 (Freeman San Francisco and Reading, October 1974) £7 80

THE main purpose of this book is to demonstrate that physical facts which are usually explained using field theory can also be explained on the basis of action at a distance between particles

The book is concerned mainly with electrodynamics (both classical and quantum) and with the masses of particles, which are treated as arising from interparticle action in accordance with Mach's principle No attempt is made to give gravitation an action at a distance form and the identification of the gravitational field with the metric is retained

The direct interaction between particles is symmetrical in time, but to this must be added the effects of the 'response' of the rest of the Universe To be consistent one must obtain a cosmological model in which this response can lead to the usual purely retarded interaction In the case of the electromagnetic interaction this condition requires that the Universe be a perfect absorber in the future Of the usual models those satisfying this condition are static universes, the closed Friedmann model, and the steady state model' The static models can certainly be rejected on observational grounds, and most people, including apparently the authors of this book, would now also reject the steady state model In spite of the statement to the contrary on page 174 (which is based on the misleading principle of taking the Einstein–de-Sitter model as typical of the Friedmann models) the closed Friedmann model also satisfies the response condition for the mass field The authors, however, reject this model on the grounds that although retarded potentials are consistent, so are advanced potentials, so that the cosmological model does not define the direction of time Their conclusion is thus that the Friedmann models must be rejected altogether in favour of some more complex model, not specified in detail If, however, the choice were between abandoning the Friedmann models and deriving the direction of time from some source other than cosmology (such as thermodynamics) then I think most physicists would choose the latter

I have concentrated on the book's discussion of cosmology, since this seems to be crucial to the whole theory The book is, however, by no means written solely for cosmologists and it contains much to interest a wider audience I doubt, thought, that it will convert many to the action-at-a-distance viewpoint   **G. J Suggett**

Everyman's Astronomy Edited by R H Stoy Pp 493+48 plates (Dent London, January 1975) £4 50

ANYONE who has followed the development of astronomy over the past few exciting years will realise that this otherwise excellent book is about four years out of date Black holes are not even mentioned in the index, X-ray sources receive scant attention, and even the discussion of pulsars is most notable for its omissions Perhaps most seriously of all, given the readership for which the book is clearly intended, the recent probes to Mars (Mariner 9), Venus and Mercury (Mariner 10) and Jupiter (Pioneer 10 and 11) all produced their dramatic new data after *Everyman's Astronomy* was ready for the press

There is, of course, a reason for this unfortunate gap The volume, intended to replace the successful *Astronomy for Everyman*, was conceived in 1960 when several chapters were commissioned, but was later abandoned until 1969 when Dr R H Stoy was called upon to complete the project As he says in a preface, "the epoch of the book as a whole is approximately 1970", but further delay arose because of the need for extensive editing to ensure homogeneity and to reduce any overlap in contributions gathered over the best part of a decade

With hindsight, there is no doubt that the publishers would have done better to wait for another few years

and produce the definitive book of its kind for the late 1970s The present round of exploration of the Solar System is now complete, and there is likely to be a lull until Mars landers, and the passage of Pioneer 11 past Saturn, revive interest in the late 1970s In other areas of astronomy, the entire electromagnetic spectrum is now open to view from satellites, including γ rays, X rays and infrared radiation, so that again we are standing at a watershed in the development of the science

But the failure of the book to have caught just the right tide in the affairs of astronomy only assumes importance because what is covered here is covered so well With nine first rate contributors, including Professor V C Reddish, Professor Z Kopal and Professor David Evans, it would have been surprising had the text not been of a high standard The illustrations—photographs and line drawings—complement the text well, and with nearly 500 pages of lightweight paper packed into the volume of a pocketbook the only notable omissions are those caused by the publication delays

Not least among the assets of the book is its price, which puts it well within the reach of all serious amateur astronomers They would be well advised to acquire this book But even though it is aimed at such readers, not a few professionals (and certainly all astronomy students) are likely to find it valuable for its compact presentation of a wealth of basic data

John Gribbin

Semiconductors

Amorphous and Liquid Semiconductors Edited by J Tauc Pp ix+441 (Plenum London and New York, 1974) $33 60

INTEREST in the field of amorphous semiconductors has increased rapidly during the last 10 years because of the obvious commercial success of the Xerox process and the possible commercial success of the amorphous switching device Before that, technical interest in the amorphous state was sustained by those interested in photoconductors as potential light sensors and in glass technology, and fundamental studies derived largely from interest in the liquid state and in the development of general methods for defining order and disorder in solids

The graph of interest against time has probably now flattened off and major discoveries are appearing more slowly, meanwhile, several reviews of the field have appeared in book form It is a good time to ask if these books tell us whether we have got anywhere in understanding amorphous semiconductors, and whether it is worth sustaining any interest The questions come to mind because the first clear message from all of the works is that the fundamental problems of under-

standing amorphous solids are very difficult, and the experimental problems, such as control in preparation and the significance of measurements, are considerable Will the strenuous efforts which are still required to solve the problems repay us to a similar extent as, say, an equal amount of work on new crystalline semiconductors?

The collection of chapters edited by Dr Tauc certainly has the depth to give the reader a chance to address the question the extensive and thoughtful reviews are presented by some of the most respected workers in the field To this depth the editor has added a suitable breadth by selecting authors who have a suitable diversity of viewpoint Some freshness is added by the inclusion of authors who have not yet received very wide exposure

Bagley, a less well known author, draws a distinction between glasses and other amorphous materials, emphasising that the structure obtained from the cooling of a liquid will be "structurally and thermodynamically related to that liquid" but that similarities between those glasses and "other amorphous solids" may be tenuous Such a caveat is a useful corrective to carry into the other chapters, which seek mainly to explain the electrical and optical properties of that class of 'other amorphous solids'

Of the chapters which review large volumes of data, Tauc's and Fritzsche's are excellently condensed, although Tauc sometimes relapses into single-sentence listing without further observation and, in the end, shirks a conclusion Fritzsche, by contrast, ends his chapter on electronic properties with a precise and frank summary of the gulf which still exists between experiment and theory in the field of electrical transport He stresses that many amorphous semiconductor films contain heterogeneous voids and that this may invalidate many of the theories based on measurements of conductivity, elastoresistance and thermopower

In his second chapter, Fritzsche gives a summary of the chemical requirements for the components of a switching or memory alloy In such paragraphs, one feels that one is getting the distillation of a huge amount of research in a few sentences and that the book is thereby achieving its intention—that of a mature review

Girgorivici has managed similarly to condense knowledge in a lively review of the mode in which atoms pack and bond in known amorphous materials Econonomou, Cohen and others give a highly condensed summary of the necessary band and percolation theory

The book represents a useful reference volume and is a very good starting point for those who wish to understand the field   **A. G. Holmes-Siedle**

Affinity chromatography

Affinity Chromatography By C R Lowe and P D G Dean Pp xi+272 (Wiley-Interscience London and New York, September 1974) £6 25

THIS book would be a valuable asset to any research group working in fields such as enzymology and protein chemistry in which an awareness of the principles and potentialities of affinity chromatography must now be considered obligatory The original literature on affinity chromatography is now considerable and an introductory text was badly needed Both the length and the price of this book have been well judged

The reader should not be put off by the first part of the introduction in Chapter I as I almost was It consists of three pages on protein structure, which are entirely superfluous for anyone who is at all familiar with proteins, and which certainly would not help anyone who was not The flavour of those three pages is unfortunate, for example, the common acidic and basic groups of amino acids are wrongly assigned as in the worst undergraduate texts, peptide bond formation is stated to "occur" by elimination of a water molecule, of all things, and that is illustrated by a "lasso" in Fig I 1 The structure of the indole ring of tryptophan (Table I 1) is wrong and the hydrogen atom of the imidazole N–H bond is missing, as indeed it is throughout the book

Happily, after that the presentation improves dramatically Most sections provide a short but helpful discussion of theoretical aspects followed by interesting examples well illustrated by elution diagrams and by structural formulae where appropriate This is particularly helpful in a book that deals with many different types of molecules and which is aimed at a wide readership that must include people not normally used to thinking in molecular terms Although many of the theoretical sections are, of necessity, brief they do provide very useful starting points for further reading All sections of the book are well supported by literature references up to mid 1973 Following an introductory chapter, there are four main chapters These deal with the principles of affinity chromatography, group specific absorbents, various applications of affinity chromatography, including hydrophobic chromatography, and the organic chemistry of materials used in affinity chromatography, particularly the reactions involved in the preparation of various affinity adsorbents   **K. Brocklehurst**

To follow
a flow

Flow Visualisation By Wolfgang Merzkirch Pp viii+250 (Academic New York and London, October 1974) $26 00, £12 50

THE need for reliable and accurate methods for rendering fluid flows visible arises in a wide variety of situations in aerodynamics, chemical engineering and fundamental experimental studies in fluid dynamics Many different techniques have been developed over the years and major advances in the subject have occurred quite recently For that reason alone there has been a need for a book which collects together all these techniques and brings the subject up to date This book fills the need adequately In an exhaustive survey the author describes, with the appropriate theoretical background, the methods from many fields, and he identifies the conditions and parameter ranges under which each method is applicable

Merzkirch divides the subject into three classes over half of the book is given over to the classification which is concerned with the various optical arrangements available for obtaining both qualitative and quantitative information from fluid flows This classification, which is headed rather loosely "Optical methods for compressible flows" (even though, in fact, several of these methods have been successfully used in incompressible flow situations—schlieren systems in salt stratified fluids, for example) describes in detail techniques such as shadowgraph and schlieren arrangements which are based on the change in refractive index of a fluid as a function of density There are particularly interesting contributions on holographic flow visualisation and the laser-Doppler anemometer, though it is doubtful whether its inclusion in this book is strictly justified

The second division comprises techniques which rely on the addition to the flow of foreign material such as dye Attention is given to the basic criterion that the flow should not be disturbed by either the mode of injection or by the material itself, and a series of empirical rules, ranges of validity and necessary corrections are given for the various methods This section, which is descriptive in character, contains useful information on the more recent innovations such as temperature-sensitive paints, liquid crystals and flash photolysis, as well as coverage of the more traditional methods

The remainder of the book is taken up with a discussion of special problems and techniques and a third classification

headed "Flow field marking by heat and energy addition" The methods described in the book cover a very wide range but are confined essentially to laboratory scale flows For completeness it could have included some of the special techniques used in larger scale field observations (estuary flows or oceanographic phenomena, for example)

Nevertheless, the book is well written and contains a large number of excellent photographic illustrations, and it will be very useful to experimentalists working in many branches of fluid dynamics   **P. A. Davies**

Life time
of an organism

Living Clocks in the Animal World (A Monograph in American Lectures in Environmental Studies) By Miriam F Bennett Pp xiii+221 (Charles C Thoms Springfield, June 1974) $11 75

CIRCADIAN and other biological rhythms are attracting increasing attention every year Strictly speaking, however, we still do not know how their extraordinary 'clock' properties are achieved The majority of investigators, myself included, consider that the timing of circadian rhythms is derived from the chemistry and physics of the cell or organism At least one laboratory, however, led by Professor F A Brown, believes that the timing is provided by "subtle geophysical factors" associated with the solar day, and, incidentally, not excluded in most experiments

The author of this small volume has been one of Brown's associates, and when I opened the book I expected to find that she pressed the second of these views She presents both cases quite fairly, however, and interprets many of the phenomena in endogenous terms She points out that the 'exogenous school' does recognise that organisms are "equipped with cellular clocks", and that the 'endogenous school' recognises that environmental variables, particularly changes in light intensity and temperature, can modulate overt rhythms in a manner which is distinct from their rôles as entraining agents She considers, perhaps correctly, that a "spectrum" of clocks from "purely" endogenous to "purely" exogenous exists in the animal world

Her material is, however, limited to those groups which she knows best, and she ignores almost totally the work done on birds, mammals and insects, which has provided most of our knowledge on circadian systems For this reason, I would not recommend it to any of my students   **D. S. Saunders**

Biochemistry

The Development of Biochemical Concepts from Ancient to Modern Times
By Henry M Leicester Pp 286
(Harvard University Press Cambridge, Massachusetts, 1974) $15 00

THIS is a book which was very much needed, and happily Professor Leicester has made a real success of it Apart from a group of lectures at the Cambridge Biochemical Institute, recently published, the only thorough treatment of the history of biochemistry was the book by F Lieben, *Geschichte der physiologische Chemie,* published 40 years ago . Lieben's book has been reprinted in recent times and will always have its value, but it is not satisfying nowadays for a number of reasons For example, he disposed of the entire period down to the end of the 17th century in only 20 pages out of a total of 700, then he divided the main body of his text into physiological topics, which were followed by an account of discoveries in the present century grouped under proteins, carbohydrates and fats The attitudes of the early thirties are very dominant, and as a whole the work lacks historical perspective

This state of affairs is now vastly improved upon in Leicester's book Eighty pages are devoted to the period from antiquity to the end of the Middle Ages, 45 to the 17th century and the time of iatrochemistry, and the remaining 105 to biochemistry, as the child of modern chemistry and modern biology The book is well informed in classical and mediaeval history, yet comes down as far as the discoveries about the genetic code made by Watson and Crick in 1953, the latest references being to work in 1971

The discussion of the ancient Western world draws from the pre-Socratic philosophers and the Aristotelians, with a paragraph or two on Alexandrian 'alchemy' Far beyond the ken of Lieben, there is a good chapter on biochemical ideas in ancient China and India, now rightly regarded as necessary because of their great influence on Arabic culture, without a consideration of which the history of any science in post-mediaeval Europe can never properly be understood Leicester has a clear appreciation of their macrobiotic drive, as opposed to the more metallurgical aurifictive and aurifactive approach of the Hellenistic papyri and the Corpus writers, respectively The Arabic chapter is also well done, though perhaps the ideas in the Jābirian Corpus (p 56) are passed over a little too quickly On the other hand, it is a good idea to emphasise the dawning of the ideal of the necessity of quantification, which occurred in the late Middle Ages with men such as Nicholas of Cusa

It has been said that most of the early history of biochemistry can be followed by tracing all the peregrinations of certain fundamental ideas—such as *pneuma,* element, humour, *krasis,* quintessence, elixir, conjunction and ferment Only four of these are actually in Leicester s index, but two more of them are fairly readily found within the text, and the reader can easily add the references to the index in his own copy Although the Paracelsian chapter is so good, with its explanations of 'chaos', 'tartar', 'iliaster', and 'arcanum', one would like to have seen the concept of 'elixir' followed through somewhere, and again the ancient idea of the *conjunctio oppositorum* lying at the basis of all affinity theory, could also have been brought in with advantage The great influence of the first distillers of strong alcohol is relevant here, since *aqua ardens* seemed indeed to be an instance of the "marriage of fire and water"

As an offering towards a second edition, I would express regret at the attribution of the discovery of gluten only to Grimaldi in 1665 (p 118), since *mien chin* had been systematically prepared on a nation-wide, if not indeed an industrial, scale in China for at least a millennium before Indeed, the discovery may well go back to the second century BC if the traditional ascription to Liu An and his circle turns out to be justified I would also like to see a rewording of the statement on p 49 that a characteristic feature of Chinese medicine was its reliance on herbal medicines This is particularly misleading because the Chinese in their pharmaceutical natural histories from the second century BC onwards never shared the Galenic abhorrence of non-herbal remedies From the beginning their physicians made much use of mineral drugs, and animal products were 'officinal' from the beginning Thus, no Society of Chymical Physitians was ever necessary to awaken the Chinese from their Galenic slumbers, they had always been awake to the three kingdoms

A great attack on Galenic orthodoxy took place when the specific virtues and specificity of drugs, as opposed to the unspecific adjustment of 'peccant humours', were recognised in the 16th and 17th centuries (pp 86, 98) It might have been good to instance at this point the remarkable career of the Cambridge 'quack' physician, Talbot, who administered quinine widely and with great success in defiance of the reigning doctrine Still later we get involved in the vitalism-mechanism polemics of the 19th and 20th centuries Perhaps it is not quite enough to end the discussion (p 159) by saying that "with the accumulating mass of chemical and physiological information

vitalism gradually disappeared from biological thought" Would not a page or two of the current debates, centering round 'reductionism', have been in place here? They contain much of great interest for the philosophy of science, and the general position of organicism is so significant in the light of more than 2,000 years of past history, that this might well have been expanded Lastly, I should like to offer to the author for a footnote in his second edition, the tradition that the invention of the term 'hormone' (p 228) actually occurred in the Hall of Caius College at Cambridge, when Bayliss and Starling were dining at High Table and had a conversation about a word they were looking for with the Greek and Latin scholars who were of the company

Professor Leicester's book is well provided with exact references, the absence of which was one of the worst features of Lieben's book The new book can be recommended without reservations to students and research workers alike, but of course it is not the last word on the subject One can see a place which could be filled by something at one and the same time more philosophical and more industrially-oriented than either Lieben or Leicester, meanwhile let us be grateful for this book   **Joseph Needham**

Developing form

On Development: The Biology of Form.
By J. T. Bonner. Pp. 282. (Harvard
University Press, Cambridge, 1974.)
$10.00.

Do not expect to find here a fashionable account of developmental biology
in terms of molecular mechanisms controlling transcription and translation,
or specificity of cell surfaces, or automata theory. For this book attempts to
deal with developmental biology in a
very broad manner, by considering not
only mechanisms in a general way but
by considering also the problems of
evolution and population biology.

Bonner attempts to do this by
emphasising the importance of life
cycles, which he believes throws new
light on basic problems. He views, for
example, biological reproduction in
terms of reproduction of the life cycle
and this theme is expanded in the first
part of the book to discuss size increase in evolution, senescence, variation, the origin of life multicellularity.
An essential feature of a life cycle is
not only to reproduce a new cycle, but
to get rid of the old one, and he thus
argues for programmed senescence. (No
mention is made, however, of Hayflick's
studies on the limited life span of
somatic cells.) Some attention is given
to looking at life cycles as having points
of maximum and minimum size, and
size increase during evolution is discussed in some detail from the point of
view of selective advantage. There is
also a quite long digression on the
origin of social organisms. His aim is
to say something about the larger
significance of development, such as
why development occurs, how it
evolved, and its relationship to all other
aspects of life. Interesting though this
biology may be, I have not found viewing it in terms of life cycles very
helpful, nor do I consider it to be an
advance over the distinction between
genotype and phenotype. By looking at
the selective advantage of the phenotype he misses the really interesting
questions on the relationship between
evolution and development. What we
want to know is what constraints and
integrations development provides when
the genotype changes. How, for
example, do new cell types arise? What
is the selective advantage as they are
evolving? One can ask the same question of the evolution of structural
innovations such as the wing. Again,
what sort of changes in genotype are required in the alteration in the pattern of
muscular activity. Must one alter genes
controlling both nerve and muscle, or
will developmental mechanisms provide
the required integration? Could one by
appropriate selection evolve a bat-like
wing for man? Dobzhansky has said
no, and thus man has no hope of

becoming an angel, but I do not believe
current theory permits a decision. None
of these problems is even recognised in
this book.

The second part of the book is concerned with the mechanisms of development and covers topics such as
synthesis of substances, timing, localisation of substances and control of
pattern, and is rather disappointing.
Part of the difficulty is that Bonner
seems much more at home with
protozoa, fungi, slime moulds and
plants. This may account for the fact
that most of the examples are drawn
from such fields and not only are they
less familiar, but in general, much less
is known about them. This also
accounts for the rather cursory treatment of topics such as microtubules
and microfilaments and cell movement
in general. One could argue that for
animal development this was an area of
major importance in which rapid
advances are being made. Other areas
such as clonal analysis, which are being
applied with remarkable success to
insect development are not even mentioned.

The book is characterised in places
by a regrettable lack of rigour. For
example, the brief analogy drawn
between the brain and the structure of
the genome is very superficial, in that it
would be as true of a juke box. Again,
a principle of convergence is invoked
to suggest that particular biological
functions in development can be fulfilled in a variety of ways; but no
attention is given to a principle of
conservation which would suggest that
once embryos have found a good way
of doing things they will continue to
use it. In fact, one of the major failures
of the book is to bring out common
features and general principles in
development. Yet again, the author
suggests that it is a distinct selective
advantage for the grouping of developmental events into superunits of gene
action, but very little evidence is available to substantiate such a view: the
interconnectedness of genes remains a
major problem and is not seriously
analysed here. Later, he suggests that
there are not enough genes to account
for all individual neurones, completely
ignoring the tremendous combinatorial
possibilities of gene networks which
could easily and uniquely characterise
each neurone with a relatively small
number of genes.

In spite of these criticisms, the author
draws on a wide range of biological
examples and his ideas are often provocative and original. By raising problems ranging from the development of
the social behaviour of ants to the form
of mushrooms he presents to developmental biologists problems and ideas
that rarely cross their minds.

Lewis Wolpert

Seals, monkeys, apes and rabbit

A COMPREHENSIVE work on British seals is long overdue and one by an authority as eminent as the late Emeritus Professor H. R. Hewer is particularly welcome*. Although seals are among the largest of British mammals, before the last war comparatively little was known about them. Since 1947, however, an increasing amount of research has been undertaken and the published results form the backbone of this book. Hewer started his own research in 1951 and during the following years he visited all the major British colonies, with the result that this is no 'scissors and paste pot' work; it is something that not only bears the stamp of genuine knowledge, but also includes many personal observations.

The first chapter is devoted to a brief account of the Pinnipedia and their evolution into three dissimilar families; it also describes their anatomical features and shows how these have become adapted to a marine environment. The main part of the book concentrates on the life history of the two seals that breed in Britain, namely the grey seal *Halichoerus grypus* and the common (or harbor) seal *Phoca vitulina*, and it is a measure of the present state of knowledge of these animals that, whereas the grey seal warrants nine chapters, information about the common seal can be contained in two.

The remaining seals on the British list are also discussed and short accounts are given of the walrus and the four species of phocids that appear

as vagrants. Mention is made, too, of the occasional 'escaped' Californian sea lion.

A final chapter which deals with the vexed question of seal conservation and management, should be compulsory reading for all those who think of seals only as appealing white-coated babies. Five appendices and a comprehensive bibliography complete the book.

There are numerous illustrations and maps, some of the most useful being Hewer's own line drawings. The photographs vary in quality and, although some of the 'chalk and soot' can be excused on the ground of enlargement from colour film, at least two have already been reproduced much more successfully elsewhere.

My most serious criticism is levelled at Appendix D and, as the source of the basic data, I think it unfortunate that Hewer did not consider other possibilities before publishing his theories. There are other minor errors which someone with an intimate knowledge of a particular colony is bound to discover, but, these apart, *British Seals* is a book that can be recommended to anyone, whether amateur or professional, who is interested in these controversial mammals.

Grace Hickling

ONE of our most pressing problems, so we are continually told, is our aggressiveness. Let it rip and you may end up with a lifer, bottle it in and you get ulcers. The answer, they say, may lie with the monkeys. Although competition for food or attractive females is common in most natural groups and the majority of species possess the

equipment for easy murder, killing and serious wounding are rare. Holloway's book† provides no panaceas and includes little material of direct relevance to human aggression. It does, however, draw together current knowledge of several aspects of aggression in primates.

Seven chapters describe the patterns, distributions and contexts of aggressive interactions in different primate taxa: tree shrews, nocturnal prosimians, diurnal prosimians, ceboids, colobines, cercopithecoids and pongids. A further two describe the reactions of rhesus monkey groups to the introduction of additional animals. Two important, if obvious, themes recur throughout these chapters. First, aggression is the means by which individuals maintain access to food, females and territories. Second, the frequency, context and distribution of aggresive interactions differ between species, between populations of the same species and (though it is hardly emphasised here) between individuals; in most natural populations of primates, aggression is both flexible and adaptive. Both points need to be borne in mind when we consider our own predicament.

A general weakness of this group of chapters is that too much space is devoted to the description of trivial interspecific differences in aggressive behaviour and too little to the generalisations and theoretical implications arising from the surveys. The excellent chapter by Nagel and Kummer on cercopithecoids (Old World monkeys) is a marked exception and emphasises how much more is known about the behaviour of this group compared with the others.

Research on the effects of androgens, brain stimulation and neural lesions on aggressive behaviour is reviewed, and interspecific differences are related to variation in neuroanatomy. These reviews show that behavioural aspects of research in this field lag some way behind naturalistic studies in sophistication (though the automatic recording systems described by Maurus offer the possibility of a speedy reversal of the situation). The effects of physiological manipulations on aggressive responses given in different contexts or to different classes of individuals are rarely distinguished, and the numbers of animals tested are usually extremely small. This is an important weakness as there is evidence that the physiological controls of aggression are both complex and variable: that is demonstrated by the useful review of the effects of androgens by Rose *et al.*

---

*British Seals. By H. R. Hewer. Pp. 256+24 plates. (Collins: London, November 1974.) £3.50.

†*Primate Aggression, Territoriality and Xenophobia*. Edited by Ralph L. Holloway. Pp. xiv+513. (Academic: New York and London, 1974.) $29.50.

Two final chapters by J. P. Scott and C. R. Carpenter review the field on a wider basis. Both are more concerned with easy generalisations about primate aggression—males are more aggressive than females, aggression occurs in competitive situations and is influenced by crowding or changes in group membership—than with important problems. That is a pity, because several theoretical problems occur throughout the book and require detailed consideration. Just what is aggressive behaviour? (It is defined in at least 10 different ways in as many chapters). Is predatory behaviour controlled by the same mechanisms or not? Should aggression include threats and displays or just physical attacks? What is the adaptive significance of differences in aggressiveness? If aggression is the means by which individuals maintain access to limited resources, why do they not kill subordinates and have done with it? When discussing the functions of aggressive behaviour, too many of the contributors treat aggression as a syndrome, suggesting advantages which invoke group selection. In contrast, there is too little discussion of the adaptive significance of differences in aggressiveness between individuals or between contexts.

Finally, how much do primate studies really tell us about humans? Clearly, research on the control and development of aggressive behaviour in primates suggests possibilities which can be investigated in man afterwards, but it is not obvious that broad, comparative studies help much. Perhaps the proper way to study mankind is not through monkeys after all since man's environment differs so widely from those of other primates. Despite these limitations, zoologists and comparative psychologists should be grateful to Holloway and his contributors for providing reviews which cover a wide and disparate literature.

T. H. Clutton-Brock

Primates: Comparative Anatomy and Taxonomy. Vol. 7: *Cynopithecinae.* By W. C. Osman Hill. Pp. xxxi+934+48 plates. (Edinburgh University Press: Edinburgh, April 1974.) £25.00.

THESE days, when half the new publications in science are either proceedings of symposia or multi-authored surveys of the latest scientific wonder, a scholarly monograph written by a single author is as welcome as the sound of the cuckoo in April. Volume 7 of Dr Osman Hill's encyclopaedic series on the primates is a worthy companion to the previous seven volumes (including Volume 8 which was published out of sequence).

It is not easy to criticise a work of such length and distinction without giving the impression of cavilling, but where matters of nomenclature and taxonomy are at stake even apparently trivial issues require comment. Two main criticisms spring to mind; there is a tendency to include everything rather than to select, and to cling to the past rather than to come up to date.

To illustrate the first point: two range maps of the same two species are included, showing radically different distributions (Maps 11 and 12, *Macaca arctoides* and *M. thibetana*). To say the least, that undermines the confidence of the reader.

The second point—clinging to the past—is instanced by the use of the name *Macaca irus* for the crab-eating macaque, ostensibly for the sake of uniformity with previous volumes. Since the publication of the *International Code of Zoological Nomenclature* in 1961, the zoological nomenclature game (once a highly esoteric pursuit) has become one which all can play. Anybody with access to a museum library can see for themselves that under Article 11g(ii) the name *irus* was not properly proposed by Cuvier in 1818, and will therefore reject it. The retention of an unavailable name merely tends to boost its status and prolong its use, thus perpetuating nomenclatorial confusion.

Turning from nomenclature to taxonomy, the same backward looking trend can be seen in Dr Osman Hill's handling of the *Macaca/Cynopithecus* controversy. In 1969 Fooden showed convincingly that the seven species (or subspecies) of Celebes macaques are monophyletic, probably an offshoot of Bornean *Macaca nemestrina* stock by way of the Makassar Strait. The species at the centre of dispersal, *M. tonkeana*, seem to be the least differentiated, and the terminal species in the north (*M. nigra*) and in the south-east (*M. brunnescens*) are, as might be expected, the most highly differentiated, and are linked to *M. tonkeana* by intermediate populations. Mayr, whose ideas on systematics and the origin of species have been widely adopted, would undoubtedly interpret these forms as congeneric. To quote from his book *Systematics and the Origin of Species from the Viewpoint of a Zoologist* (Dover: New York), "That they are nothing but subspecies, or at best allopatric species, is particularly evident in cases in which the widely diverging species are the extreme ends of a long chain of intermediate subspecies."

Nevertheless, Hill still feels it necessary to give taxonomic expression to the extreme differentiation of the northern Celebes 'Black Apes' (*Cynopithecus*) from the Moor Macaques (*Macaca maurus*), following Laurie and Hill (*List of land mammals of New Guinea, Celebes and adjacent islands, 1758–*

1952. Trustees of the British Museum, Natural History, London). But contrary to Laurie and Hill, the watershed between the two genera has been shifted further south so that *M. tonkeana* (considered by Laurie and Hill as a synonym of *Macaca maurus*) is now arbitrarily assigned to the genus *Cynopithecus*. Arbitrarily? I am afraid so, because no convincing data are given to back up this decision, without which it can carry no weight. It merely serves further to embroil the reader in the confused taxonomy of the group.

The present volume will undoubtedly be welcomed, particularly by applied scientists for whom the macaque monkey is still the centre of the experimental universe. The information and sources that Dr Osman Hill supplies are invaluable to all research workers who will continue to regard his series as the most authorative and definitive available. One will not see its like again.

John Napier

The Biology of the Laboratory Rabbit. Edited by Steven H. Weisbroth, Ronald E. Flatt and Alan L. Kraus. Pp. xi+496. (Academic: New York and London, 1974.) £23.75.

THIS is the first comprehensive text devoted solely to the laboratory rabbit, and it will prove to be of value to a wide variety of scientists concerned with the use of this species as an experimental animal, or who are engaged in the practice of laboratory animal medicine and husbandry.

There are 25 contributors (all from the USA) who provide 18 chapters. The text is supported by numerous illustrations and tables, together with a comprehensive list of references at the end of each chapter.

Chapters 1–3 consider basic aspects such as genetics, husbandry, anatomy, physiology and biochemistry. Additional genetic information is given in chapters 7 and 15, which are devoted to serological genetics and inherited diseases and variations.

More than half the book (11 chapters) is devoted to disease, parasitic infections and pathology, and successfully amalgamates much of the literature scattered throughout scientific proceedings and journals.

Chapter 4 is concerned with biomethodology and details many basic techniques and procedures.

Chapters 5 and 6 contain comprehensive reviews on the rabbit foetus in experimental teratology and on arterio-sclerosis research, and chapter 8 provides a sound introduction to gnotobiology.

Any attempt to consolidate information economically will leave gaps, and this book is no exception. Nevertheless, it can be thoroughly recommended for study and reference. **John Bleby**

Everything caudal to the eyes

Handbook of Sensory Physiology Vol. VII/3: Central Processing of Visual Information. Parts A and B. Editorial Board: H. Autrum, R. Jung, W. R. Loewenstein, D. M. Mackay, and H. L. Teuber. (Springer: Berlin and New York, 1973.) Part A: pp. xi+775; part B: pp. viii+738; DM 248 each.

NOT one book but seventeen (at the latest estimate), and each one so weighty that a single hand can hardly lift it. That is the *Handbook of Sensory Physiology*. It will probably exceed 13,000 pages with more than 4,000 illustrations and is undoubtedly intended to be a definitive statement of the progress of research on sensory systems. The list of authors is massively impressive, the production lavish, and the coverage catholic almost to the point of being indiscriminate.

Volume VII is devoted to vision and I am particularly concerned with Volume VII, Part 3, two large tomes which tackle the *Central Processing of Visual Information.* It is edited by Richard Jung, the father of the Freiburg school of neurophysiology, where work on the visual cortex began 25 years ago with the explicit motive of seeking explanations for perceptual phenomena in physiological terms. That theme is well represented in these books, which cover everything in the visual system caudal to the eyes.

Professor Jung opens Volume VII, Part 3, Part A, Section 1, Chapter 1 (believe it or not) with an encyclopaedic account of the successes of his own approach to the visual system, particularly concerning the role of so-called 'B' (brightness) and 'D' (darkness) neurones in determining the perception of brightness and contrast. This chapter alone is about 150 pages long and together with two other chapters of 100 pages or more (by Grüsser and Grüsser-Cornehls on movement perception, and van der Grind *et al.* on temporal transfer properties) it dominates the first book.

In Part B there are five especially valuable comprehensive chapters: Sprague *et al.* give a much needed, up-to-date account of the functions of visual projections to the tectum; Freund covers the physiology of the lateral geniculate nucleus; Brooks and Jung do the same for the visual cortex; and Szentágothai reviews the structure and ultrastructure of both the geniculate body and the cortex in two chapters that are as pleasing to the eye as they are to the rest of the nervous system caudal to the eyes.

It is the major reviews that give this work its historical importance, of course, but I enjoyed the books more for some of the shorter, more personal chapters on specialised topics: MacKay on the stability of the visual world, Levick on spontaneous and maintained neuronal activity, Gross on the inferotemporal cortex and Brindley on stimulation of the human visual cortex.

All these and many other fine chapters make the books indispensable for any library of physiology. Not that the whole venture is without fault. In general, the books suffer dreadfully from the lack of overall organisation that so often mars multi-author works. In fact, the degree of overlap and even straightforward contradiction between chapters, and the whimsically random systems of referencing make the books frustrating to read. The few chapters on visual processing in lower animals, although excellent in themselves, seem an incongruous sop to comparative physiology. Where is the essential review on the analysis of visual information (not just colour vision) in insects, spiders, octopus, crayfish and so on?

Finally, I am disturbed at the price: £45 for 800 pages. I believe that books of this sort ought not to cost so much; the libraries that will have to take the whole series are going to have to pay a vast sum. It raises in my mind doubts about the role of purely commercial enterprises in the essential business of disseminating scientific results. **Colin Blakemore**

Into the cell

The Cell Nucleus. Edited by Harris Busch. Vol. 1, pp. xxiii+667; vol. 2, pp. xxiii+564. (Academic: New York and London, July 1974.) $45.00; £21.60 each.

DR BUSCH has courageously attempted to collect together all the important knowledge about the eukaryotic nucleus and it has required 59 authors, many of whom have made fundamental contributions to their subject, to write the 39 articles. It is interesting to draw comparison with a similar major work, the six volumes on *The Cell* (Academic: London, 1959–64) which were almost exclusively devoted to the cytoplasm; and with a slim volume, *The Cell Nucleus* (Butterworth: London, 1960). Our knowledge then was quite primitive, but at about that time two fundamental observations were made which have led to the development of important new techniques and thus to many of the discoveries now described.

First, Marmur and others showed that it was possible to separate the two strands of the DNA molecule and then to reassociate them, a process depending on pairing between complementary sequences of the nucleotide bases. This

technique of reassociation, or hybridisation as it is called when the DNA chains are from different organisms, or involves an RNA chain, has led to a new understanding of the nature of the base sequences, their repetition and their location, in the very long DNA molecules thought to comprise each eukaryotic chromosome. In Busch's volume seven articles refer to various aspects of this problem and Strauss makes useful comparisons with the genomes of bacteria and viruses. The most thoroughly understood sequence is that coding for ribosomal RNA (Choi, Nazar and Busch), but the article on the fine structure of the site of its transcription, the nucleolus, may leave readers in a confused state because of the lack of a suitable schematic diagram and because of the variation in the terminology used for the different zones.

Second, in 1960, Barski discovered the spontaneous hybridisation of different cell types. Cell fusion has been called "the new gift to biology" and the reasons will become clear from Sidebottom's excellent article on heterokaryons. Cell fusion is the analogue of gamete fusion and Kucherlapti, Creagen and Ruddle describe its use in genetic analysis of somatic cells. The genetic content of the nucleus can also be studied by implantation into eggs and Gurdon summarises his elegant experiments which show that cell differentiation is not accompanied by loss of, or permanent alteration of, genes.

Five articles, including a lucid, basic introduction by Arrighi, provide a comprehensive survey of mammalian metaphase chromosomes and their recently discovered banding patterns. There are, however, numerous texts on these topics and the article showing clinical pictures of the effects of chromosome imbalance could have been omitted to help reduce the high cost of these volumes. Substantial articles deal with heterogeneous and other nuclear RNAs, nuclear proteins and DNA polymerases, and DNA-dependent RNA polymerases. Franke and Scheer, and Kasper, have contributed extensive and detailed articles on the nuclear envelope and their enthusiasm is evident from the number of recent results added in proof. There are also excellent chapters by Edström and by Hennig on polytene chromosomes. An aspect of chromosome structure, other than the base sequence, is the way in which the DNA molecule is folded up in association with proteins, and Solari skilfully steers us through the complexities, but unfortunately the book is already too out of date to include exciting new results on *v*-particles, nuclease-protected fragments and so on.

The Cell Nucleus contains most of the relevant material conveniently collected in one place (in addition to those mentioned the volumes include a number of other valuable articles) and will be an important source of references. Some subjects are, however, controversial—for example, the nature of heterochromatin—or complex—like repetitious DNA and its possible functions—and readers no doubt will feel a real need to consult the dozen or so annual reviews where related and sometimes more lucid articles can be found. Most chapters are very specialised and won't be suitable for undergraduate study.

There is no doubt that the books, which seem at first sight formidable in their bulk, would have benefited greatly from a good historical introduction outlining the important discoveries and showing how articles were chosen so as to fit into the general scheme.

Howard G. Davies

Plants and salts

Ion Transport and Cell Structure in Plants. By David Clarkson. Pp. xi+350. (European Plant Biology Series.) (McGraw-Hill: London and New York, April 1974.) £6.95.

This is the first book on plant–salt relations I have seen which takes full account of the advances in the subject which have been made in the last 10 years. In this respect it makes some recent American texts look distinctly old fashioned.

Here the undergraduate, for whom the book is intended, can read about isotope washout curves, the electrochemical approach and the chemiosmotic hypothesis, topics which have not been seen together before in a book of this type. The first six chapters are concerned with the cellular level and include an excellent chapter on the cell membrane. To illustrate the principles Dr Clarkson frequently refers to the alga *Hydrodictyon africanum* as a model; a good idea for an undergraduate text.

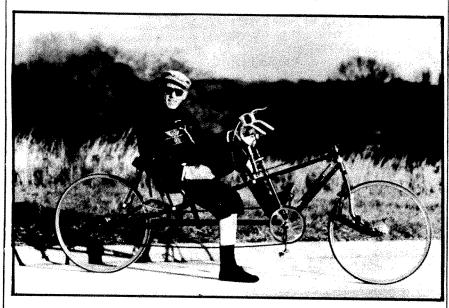
The second half of the book deals with the salt relations of the higher plant and in particular the root. It is not as well set out or as well written as the first half which one feels would make an excellent book on its own.

There are one or two errors in the text which might confuse the undergraduate such as the one on page 227 where in a discussion about the structure of the endodermis the reader is referred to a figure which turns out to be a scanning electron micrograph of a xylem vessel. Despite these blemishes Dr Clarkson is to be congratulated on his bold modern approach.   **D. J. F. Bowling**

Phycology and physiology

Algal Physiology and Biochemistry.
Edited by W. D. P. Stewart. (Botanical
Monographs, vol. 10.) Pp. xi+989.
(Blackwell Scientific: Oxford and
London, 1974.) £15.50.

MUCH basic physiological and bio-
chemical information on plants comes
from the study of algae, and the
general plant physiologist will be in-
terested in this book as a summary of
current knowledge on algal chemistry
and function. The phycologist's re-
quirement is also for a clear statement
of the algal situation, together with a
brief setting of the general scene so
that cross comparisons can be made
for major groups within the algae and
between algae and other plants. That
format is adopted by most of the
authors contributing to this book,
usually with marked success.

The book begins with a sensible com-
ment on biochemical taxonomy, appro-
priately enough by R. A. Lewin who
edited the 1962 *Physiology and Bio-
chemistry of Algae*, now superseded by
the present volume except as a survey
of the earlier literature; I am glad to
see Dr Lewin warn against the dangers
of generalising from studies on one
strain of one species under one set of
conditions, and of making comparisons
at class level from knowledge of a few
species out of thousands. This is fol-
lowed by comprehensive chapters on
cell walls and polysaccharides, storage


products, fatty acids and lipids, sterols
and nucleic acids. Each contains a
wealth of information correlated to the
biology and taxonomic position of the
algae concerned. In a chapter on
nuclear and cytoplasmic inheritance in
green algae, Ruth Sager confines her
account almost exclusively to investiga-
tions on *Chlamydomonas*. The result is
a chapter of substance by the expert
in the field and, since a forthcoming
title in the Botanical Monographs
series is a 250 page book on *The
Genetics of Algae*, Dr Sager is obvi-
ously right to present this account
rather than a telegraphic review of all
algal genetics.

Unfortunately, one or two chapters
attempt to summarise overlarge topics
and fail for lack of space. In the chap-
ter on cytoplasmic organelles, L. V.
Evans tries to review the relationship
between the structure and function of
f l a g e l l a, haptonemata, trichocysts,
scales, lysosomes, microbodies, con-
tractile vacuoles, walls, nuclei, micro-
tubules, nuclear division, mitochondria
and Golgi bodies, all in less than 20
pages of text. The task is manifestly im-
possible and the result is a catalogue
of truncated descriptions and oversim-
plified generalisations that seem out of
key with the rest of the book. Three
pages are devoted to descriptions of
mitotic ultrastructure in various **algae**
but there is no comment on signific-
ance, either functional or phylogenetic.
Golgi structure and function receive
better treatment but it is a pity that a
separate chapter could not have been
given to this topic, allowing room for

some interpretation and ideas in the
account of other organelles. Plastids
are given a whole chapter in which T.
Bisalputra is able to discuss, albeit
briefly, variations of chloroplast ultra-
structure in relation to algal classes and
pigments, and this is followed by chap-
ters on chlorophylls, carotenoids
and biliproteins, which satisfactorily
tidy up many of the earlier conflicting
and doubtful records (especially for
carotenoids).

Moving from biochemical to physio-
logical topics, we come to a series of
excellent chapters on light absorption,
emission and photosynthesis, photosyn-
thetic electron flow—with a fascinating
small follow-up chapter on the elucida-
tion of the electron transport chain by
the study of algal mutants—and a wide
range of other topics. Physiologists may
fight among themselves over some of
the more controversial ideas expressed
in these chapters but personally I found
them, not surprisingly, highly informa-
tive and, more surprisingly for a non-
physiologist, largely intelligible. In
cases where the technical aspects of
the subject are difficult or, frankly,
beyond me, I still found that most of
the authors were able to convey to me
the general significance of the studies
under discussion.

In a short review one can do little
more than indicate the main coverage
of the book and comment on its
general standard. The coverage is wide,
the general standard excellent. If there
are any significant errors of chemical
fact these will doubtless be commented
on in other reviews by biochemists.
There is a discrepancy between Evans
(pp. 96-7) and Nultsch (p. 866) in the
information on microtubule subunits,
even allowing for the fact that 4.5 μm
is a misprint for 4.5 nm in the latter
account; Prasinophyceae are charac-
terised by scaly flagella rather than
hairy flagella (p. 3); other errors and
misprints are few and far between.
Production is good, though some of the
electron micrographs are overenlarged,
badly printed and chopped off at the
edges. The price is high, but that is to
be expected for a 1974 book of nearly
1,000 pages.

As a nonphysiological, nonbio-
chemical phycologist, I found some
parts of this book easy and enjoyable
to read and other parts heavy going.
In relation to my research, teaching,
reading and editing interests in the
algae, the book has already proved in-
formative and stimulating. The data
summaries, formulae, tables and dis-
cussions will be invaluable for refer-
ence purposes. There is no doubt that
this book will be an essential work of
reference for years to come, both for
the phycologist and the p l a n t
physiologist.   **Gordon F. Leedale**

Captain Dan Henry, supine upon his recumbent bicycle. Captain Henry, from
Flushing, New York, became well known for his early design of sprung bicycle.
His adaptation, though somewhat cumbersome by today's standards, rendered his
machine "faster in hill climbing", and he was able to note with some satisfaction
that his tyres lasted longer. Energy conservationists take note. From *Bicycling Science,
Ergonomics and Mechanics*. By Frank Rowland Whitt and David Gordon Wilson.
Pp. xiii+247. (MIT Press: Cambridge, Massachusetts, and London, 1974.) n.p.

Biochimie. Edited by François Chapeville and Hubert Clauser. Pp. 872. (Hermann: Paris, 1974.) Fr. 178.00.

THE appearance of a comprehensive new textbook of biochemistry in French may well be met by English-speaking biochemists with an equanimity verging ever on indifference. For all that, it is an event of no little note, for creeping Americanisation has been threatening increasingly the character and individuality of European science. In most areas of research the European languages have been all but displaced by the new *lingua franca*. Very recently a discovery in a French laboratory was given wide publicity in the press, and *Le Monde* thought it worth remarking, in a tone of apparent asperity, that the work was being published in the American journal *Proceedings of the National Academy of Science of the U.S.A.* (rather, by implication, than in the corresponding French organ), and in French.

That this comment should ring so quaintly, shows how completely the realities of the situation, unpalatable as they may be, have been accepted by French (and no doubt other European) scientists in recent years. If English is the currency of research, however, it must nonetheless not be allowed to become the exclusive language of science. If French science is to preserve its own distinctive flavour and personality, matured through centuries of tradition and evolution, the language must be kept alive in the science faculties and textbooks. That in itself seems to me good reason to be grateful to the publishing house of Hermann, which has followed its admirable series of silver paperback monographs with a substantial new text, edited by Chapeville and Clauser and comprising separate contributions from 11 authors.

The publisher has secured a distinguished line-up of contributors, who have provided a well-balanced coverage. The book deals with bioenergetics, reaction mechanisms, proteins and amino acids, enzymes and catalysis, structure and metabolism of the saccharides, lipids and steroids, nucleotides and nucleic acids, intermediary metabolism, oxidation, phosphorylation, photosynthesis, biosynthesis of metabolites, and the chemistry of heredity. The treatment throughout is authoritative and clear. Some of the authors lean to a conservative view of what constitutes the established canon, and tend, therefore, to stress the classical rather than the topical.

The book is altogether not free from the inevitable drawbacks of multi-author treatises; in particular one

misses the unifying thread that a single author can at best impose by his view of the subject. There are also places in which the fields of interest do not interlock. For example, there is no mention of muscular contraction, chromatin, or nervous conduction, and the word rhodopsin is not in the index. But these lacunae are almost universal in the standard text-books in English, and I do not wish to cavil with what strikes me as a notable achievement. All of the authors have long teaching experience behind them, and many

French versions

generations of undergraduates and graduate students (myself included) have sat at the feet of most of them. They seem to me to have fulfilled their tasks admirably. And though it would be invidious to draw comparisons my personal choice for style and stimulus would be the chapters written by the two editors.

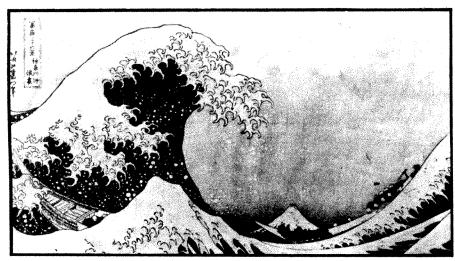
The book is attractively laid out in the modern style, with elegant typeface and attractive diagrams in pastel shades, which I hope will now generally supplant the rather stately and oppressive format, too often characteristic of scholarly works in European languages. I do not doubt that it will benefit French undergraduates, medical students and research workers for many years to come, and one may hope that translation may also render it ultimately accessible to English readers.

Anne d'Albis

Geologie de la France. Vols 1 and 2. By J. Debelmas. Pp. 1–294, vol. 1; 295–539, vol. 2. (Doin Editeurs: Paris, 1974.) Fr75.00 each.

THIS book is a series of articles written by various specialists, each of them working on one of the natural geological regions of France. In the preface, Jacques Debelmas, who dealt with the coordination of the various articles, states the ambitions and limitations of his undertaking: ". . . the problem is not only to give a perspective of the stratigraphy, and the tectonics of the various regions, . . . but to link both, so that it is possible to recognise a structural evolution through a succession of features and, on the other hand, to use this evolution when it is known, for a better understanding of these features through time and space . . .". There is another requirement, conciseness: ". . . it is a mainly didactic introduction to the geology of

France". This is not a treatise, but more a manual of regional geology for the use of students, which excludes numerous discussions and hypotheses, and long bibliographical lists.

The book is divided into two volumes. In the first, after a general introduction to the geology of France, the reader will find a description of the "Ancient massifs" — the Ardennes, Vosges, Armorican Massif and Massif Central—and a study of the vast sedimentary basins—the Paris Basin and the Aquitaine Basin—in which the pre-Mesozoic structure is depressed although the secondary and tertiary layers are only slightly deformed. In the second volume, there is a description of the folded ranges of the Alpine cycle: the Pyrenees, Provence, the Franco-Italian Alps, Jura, Corsica, Burgundy and the Rhone valley and Languedoc.


One is left with two impressions. First, the work has achieved part of its aims: because of its legibility, many illustrations, logical presentation, and also because of the care of the authors to reach the quintessence of their subjects, the book is both easy to read and interesting, and its success among students is assured. It is very convenient to have, assembled in one book, records of the large number of geological studies made in France since the last century.

The second impression which remained was of the disappointing lacunae within the book. All discussion of plate tectonics is set aside. Certainly the reader is made aware of this in the preface; but is it really defensible to omit a subject which has revolutionised earth sciences in the last few years? In addition, surface geology, easily observable, is highlighted at the expense of depth geology, which demands the indirect methods of geophysics; for example, no information is given on the thickness or structure of the crust. An analysis of seismology (which could have introduced a chapter on neotectonics), and of the interpretation of magnetic and gravimetric ideas, though essential to all structural studies, are missing. Finally, the presentation of the deep structural levels of the "Ancient massifs" does not pay enough attention to the recent results of microtectonics, the study of metamorphism (facies and facies series) and geochemistry of magmatic rocks.

This is an instructive and attractive book; but perhaps it will give students too incomplete a picture of the geology of France; and it may give foreign readers a false impression of French research in the earth sciences.

G. Boillot and R. Capdevila

Finding answers from the seas

The Sea: Ideas and Observations on Progress in The Study of The Sea. Vol. 5: *Marine Chemistry.* Edited by E. D. Goldberg. Pp. xiv+895. (Wiley-Interscience: New York and London, June 1974.) £21.20.

AT the First International Oceanographic Congress in New York in 1959, Lars Gunnar Sillén, Professor of Inorganic Chemistry at the Royal Institute of Technology in Stockholm, was invited to express the views of a laboratory chemist on the composition of sea water. His lecture, "The Physical Chemistry of Sea Water" represents a milestone in the development of ideas about the chemistry of sea water and the evolution of the composition of the hydrosphere, atmosphere and lithosphere over geological time. As Goldberg points out, the lecture was, in fact, the first of a series of investigations of the implications of equilibrium calculations of the ocean system, which challenged many prevailing notions and provided new ideas about a wide range of natural phenomena.

Volume 5 of *The Sea* is dedicated to Sillén and consists of accounts of the status of specific aspects of marine chemical research and includes chapters on completely new growth areas which have developed since Sillén's passing.

The status reports are largely contained in Part I (Thermodynamics of the Seawater System) and Part III (The Sedimentary Cycle). Millero, Disteche, Dyrrsen and Wedborg review the purely thermodynamic aspects of sea water as an electrolyte solution. Gieskes discusses the alkalinity/CO_2 problem, and confirms the confusion that arises over the use of apparent constants to describe the CO_2 system in the sea. That chapter is particularly refreshing because in addition to thermodynamic and kinetic considerations, mention is made of the influence of both sediments and purely physical oceanographical processes on the distribution of $CaCO_3$ and some other chemical parameters in the sea. Breck reiterates his own suggestion that the pE (the redox potential) in oxic seawater is governed by the O_2/H_2O_2 couple and has a value substantially different from that estimated by Sillén.

Part III is by far the largest section of the book, and starts off with a chapter by Garrels (who specifically mentions the effect of Sillén's 1959 lecture on the direction of his own research) and Perry. It is a brief summary of the main conclusions of several papers by Garrels and his co-workers, and of the book *Evolution of Sedimentary Rocks* by Garrels and Mackenzie (1971). The section also has two interesting and quite different chapters on specific problems in sedimentary geochemistry, namely magnesium (Drever) and silicon (Wollast). Chapters on diagenesis (Berner), interstitial waters (Manheim and Sayles) and sulphur (Goldhaber and Kaplan) emphasise the large amount of attention currently directed towards post-depositional reactions in unconsolidated sediments, reactions which are important in controlling the long-term composition of sea water itself.

In Part IV (The Impact of Life Processes Excluding Man), Menzel gives a timely, if partisan, review of the mass of conflicting data on the distribution of dissolved and particulate carbon in the sea, and its metabolic fate. A large amount of data obtained about 10 years ago, which was treated with some scepticism when it first appeared, is apparently reliable so that some early, hotly debated, suggestions about the carbon cycle are probably correct. The relatively new area of the chemistry of marine natural products is reviewed in depth by Faulkner and Andersen, and Lowenstam offers a lengthy account of the information available on the chemical composition of inorganic skeletal material and the impact of skeleton building on other chemical and physical processes in the oceans.

Part V (The Impact of Man on the Chemistry of the Oceans) is remarkably short in view of current interest (albeit concern) in the topic and the influence that the editor has himself had in drawing attention to it. The chapter by Jernelöv on heavy metals, metalloids and synthetic organics is very brief and inadequately referenced, and that by Preston dealing with artificial radioactivity is simply an inventory and a straightforward account of the possible behaviours of important radionuclides. Part VI (Origin of the Ocean) contains a single chapter by Arrhenius, De and Alfvén, which reviews their own recent work in several far flung branches of space research.

The most interesting contributions in this large volume are, however, contained in Part II (Air-Sea Interactions). They are interesting because they are concerned with new growth areas in marine chemistry. Thus, MacIntyre presents an iconoclastic, in places amusing, and thorough review of reactions in the sea–surface microlayer using a mass of data drawn from sources not immediately available, or indeed obvious, to marine scientists. Seiler and Schmidt, in a refreshing account of non-conservative gases in the sea, point out that the main source of nitrous oxide in the atmosphere is in fact the ocean, and that the atmospheric budgets for hydrogen, methane and carbon monoxide are affected to important degrees by processes in the sea.

This volume, although it is an invaluable addition to the series, does have some deficiencies. Specifically, the success or otherwise of the ion association and specific interaction models in describing the properties of sea water electrolytes is passed over rather swiftly. Recent work by Whitfield, Leyendekkers and Pytkowicz, for example, has given interesting new insight into the utility of some of the available models. A second almost completely neglected area which is only mentioned somewhat obliquely by Gieskes and Menzel, concerns the currently popular use of advection–diffusion models to describe and to understand the distribution of certain chemical parameters in the oceans. Whatever one may think of the usefulness of this particular approach, it has focused some much needed attention on some of the hidden effects that physical and biological processes have on the behaviour of some of the variables frequently measured by marine chemists.   **S. E. Calvert**

Deep Sea Sediments. Edited by Anton L. Inderbitzen. Pp. ix+497. (Plenum: New York and London, 1974.) $42.00.

THIS volume, resulting from the proceedings of a symposium conducted by the Ocean Science and Technology Division of the US Office of Naval Research in 1973, is remarkably comprehensive. The 23 papers achieve more than adequately the purpose of the book, to bring into sharper focus the "state-of-the-art" regarding the physical and mechanical properties of sediments and the need to establish some degree of coordination among investigators. What has had to be left out has been amply included in the references at the end of each paper which, in total, comprise a truly universal bibliography in the field of sediment mechanics.

From a panoramic viewpoint the volume deals mainly with the present situation regarding sampling devices, laboratory measurements (both mechanical and physical) and the extension of laboratory investigations to the field.

In the Atlantic, Indian and Pacific Oceans, physiographic provinces have been devised as a means of establishing some order to the quantity of mechanical data which is becoming available. Empirical equations relating mechanical and physical properties have shown minute spatial variations within each province, and carbonate distribution studies may explain some of these variations. It is, however, stressed that the provinces are not homogeneous entities and that although the mechanical/physical correlations may indicate trends, overall correlations are less accurate than those obtained for single provinces.

A number of papers deal with an extension of the correlations from laboratory/laboratory to laboratory/field, and serve to indicate that, at present, the prediction of *in situ* sediment properties and of the settlement of structures to be placed on the sea floor are woefully inadequate, with up to 30% error under ideal conditions of measurement.

Therefore, questions are posed concerning the measurements being taken. Is the macroscopic approach of the engineer good enough? Shall we ever achieve good all-round working prediction models using these macroscopic methods? The safety factor of the engineer conceals a lot of what is lacking in theory. Thus, it seems that more effort is required in a study of microstructure—so that the engineer's methods may become modified for the sediment researcher.

The urgency of the situation is stressed amply in these papers which indicate the imminence of commercial enterprise in the mining of ferromanganese deposits as a source of

Natural Gases in Marine Sediments. Edited by Isaac R. Kaplan. Pp. viii+324. (Plenum: New York and London, 1974). $30.00.

THIS volume consists of 17 chapters, which originally derive from papers presented at a symposium held at Lake Arrowhead in November 1972. The various possible sources of gas in sediment are discussed in the early chapters, together with such analytical information as is available. Because of sampling difficulties, most of the data refer to shallow water cores or to certain Deep Sea Drilling Project sites; by now, much of this information has been available in the literature for some time, but it is useful to have it presented in one volume, if only because it emphasises the restricted range of data available.

The latter half of the book is given over to consideration of the physical state of the gases in deep sea sediments, with particular regard to the possibility that gas–water clathrate compounds, or 'gas hydrates', may occur under the *in situ* conditions of low temperature and high pressure. Three chapters on the known thermodynamic properties of such compounds establish the areas of the world ocean in which these ice-like solids are stable; and as gas concentrations must be very high, some mechanisms, such as the *in situ* production of methane by the bacterial decomposition of organic material, or the injection of carbon dioxide, hydrogen sulphide, or methane from geothermal vents, must also be available.

Given that, the possible zone of hydrate occurrence is bounded on the upperside by the increase of temperature and decrease of hydrostatic pressure as the sea surface is approached from below and on its lower side by the increase in temperature

resulting from the geothermal gradient. For instance, in sea water which is 2 km deep, and which has a bottom temperature of 2 °C, it is shown that methane hydrate would be stable to a depth of about 600 m within the sediment. Although the hydrate would theoretically also be stable in the water column above the sediment at all depths below about 500 m, it is not likely that the required gas concentrations could be sustained outside the sedimentary column. Thus, the phenomenon is to be expected only within the upper regions of deep sea sediments.

Although no unequivocal proof of the existence of gas hydrates is given, three chapters describe the occurrence of sub-bottom acoustic returns which could be interpreted in such terms. Two authors also describe laboratory rigs for the formation and study of hydrate–sediment mixtures, and preliminary results are given.

One editorial function, which is particularly difficult with symposium volumes, is to ensure that a subject is covered evenly and without unnecessary repetition. The editor of this volume has included a useful and well written introduction which draws together the threads of research presented by the various contributors; it is a pity that he could not at the same time have eliminated redundancy. It is, for instance, irritating to be told five times of Humphry Davy's discovery of chlorine hydrate. The appearance of the book, apparently produced by a photo-offset process from a very superior, accurate and uniform typescript, is beyond reproach. *Natural Gases in Marine Sediments* can be recommended to all those interested in marine sedimentation, as a useful introduction to an under-explored field of study.

T. R. S. Wilson

copper, nickel and cobalt and which consider the resulting public concern over the protection of fauna and environment.

There is a need for better instruments for obtaining undisturbed samples. Box covers seem to give good samples but are at present limited to the near surface (36 cm). There is, however, an even greater need for undisturbed material from greater depths. The transport of core material, as well as the actual sampling procedure, produces varying degrees of disturbance. That, and the weakness of prediction models, has stimulated more *in situ* work.

Yet the contributors have not forgotten that their research is often

limited by economic stringency and that laboratory work relating to the deep sea environment must always play a vital role.

It is, however, pointed out that economic constraints can be lessened by means of a coordinated approach to sediment research.

There is a call also for the standardisation of techniques, symbols and units of measurement, concerning which this volume has put forward many worthwhile proposals. Standardisation would necessarily save much time and confusion.

The bibliography, data, problems and ideas presented in this volume will be invaluable for future work in sediment mechanics.   **Sinclair Buchan**

Living ancient history

Introducing Geology: The Earth's Crust Considered as History. By D. V. Ager. Pp. 256+21 plates. Second Edition. (Faber and Faber: London, February 1975.) £3.95, hard bound; £1.75, paperback.

THIS is a book about very ancient history. It reviews, in readable language, the geological evolution of the British Isles, with some references to other parts of the world. Since the first edition appeared in 1958, there has, as everyone knows, been a revolution in the earth sciences: continental drift has now been proved, and seafloor spreading, subduction and plate tectonics have all become recognised as aspects of the surface layers of a planet that is probably expanding. This new edition adds a bold but sufficient outline of these exciting developments to the first chapter and applies them at later stages; for example, the mid Palaeozoic troughs are seen as resulting from the opening of a proto-Atlantic between plates bearing America and Europe on their backs; plates which later closed to produce the Caledonian Mountains. Similarly, the break-up of the former southern continent of Gondwana under the influence of convection currents in the upper mantle is used to illustrate an important stage in geological history. In that and other ways, the reader is introduced to modern ideas of global tectonics.

The general treatment remains the same: the consideration of groups of geological epochs and systems. Thus, the chapters entitled "Oldest Rocks of All" covers the 4×10^9 years of Precambrian time; the "Oldest Rocks with Fossils", the Cambrian, Ordovician and Silurian systems; "Dry Land and Shallow Seas", the Devonian and Carboniferous. Each chapter is illustrated with maps showing the general outcrops of the relevant strata in Britain; and palaeogeographical diagrams, some original, some based on the works of L. J. Wills and F. W. Shotton, are included. There are illustrations of typical fossils but there is a minimum of fossil names and almost no mineral names. The chief rock-making and physiographical processes are described as they become relevant and they are illustrated with well produced plates, prepared mainly from Geological Survey photographs.

In one respect, Professor Ager has again been overtaken by events. His chapter entitled "The Long Quiet Episode", devoted to the Rhaetic, Jurassic and Cretaceous, was very suitably named when he prepared this second edition; as he says, it was reasonable to think of the European plate sailing peacefully at this time. But last November, the North Sea petroleum operators released their geological results, showing that the later stages of Jurassic time were not all quiet in the British area. There were in fact major rift-forming movements in the centre of what is now the North Sea, accompanied by modest volcanic activity and followed by extensive erosion. The rift profoundly affected Cretaceous sedimentation, which had filled up the trough by the time that the Tertiary basin covered it. The effects of these 'Kimmerian' movements explain the absence and reappearance of Jurassic strata in various parts of the North Sea Basin, and make us realise that the apparent continuity of the Jurassic outcrop across England is no indication of what happens in the third dimension. There will be material for a third edition of this book, but in the meantime it is none the worse for having missed the Kimmerian. Geology is, after all, a living and developing subject, and this historical approach to the country which so much influenced its progress is a good introduction to it.

Kingsley Dunham

By jove

The Jupiter Effect. By John Gribbin and Stephen Plagemann. Pp. 136. (Macmillan: London and Basingstoke, 1974.) £3.95.

" . . . all we have done is to gather in one volume data from scattered sources and look at them anew . . . "

And a splendid job the authors have made of weaving a complex, yet neat, design from the geophysical observations they have used. There may be a piece or two still missing, and the picture might well fall apart when lifted by the corner, but nonetheless it is a readable yarn which inquisitive citizens will enjoy; and seismologists may envy the authors' courage in undertaking to predict that the next great earthquake on the San Andreas Fault will occur in 1982, give or take a couple of years.

In that year the planets of the Solar System will be in conjunction with every other planet for the first time in 179 years. On the evidence of correlations—observed since the 17th Century—between peak sunspot activity and peak tides raised on the Sun, the authors predict a dramatic increase in activity for 1982. This, they argue might initiate a chain reaction through the interaction of solar wind and cosmic rays with the upper atmosphere, thereby affecting world wide atmospheric circulation patterns which in turn would change the Earth's rate of spin to provide the relatively small triggering force required to raise the 'normal' level of seismicity in highly strained belts. Observational evidence is well documented, and the circumstantial links in the chain plausibly argued. In the process the authors have provided lay readers with an educational glimpse of several geophysical processes and the geophysicist with sufficient stimuli to follow their suggestion to "wonder how such an interaction *could* work".

Why pick especially on the San Andreas Fault? Well for one thing it must attract wider interest (and a larger market) than, say, the Highland Boundary Fault and for another it is so well studied, so closely knitted instrumentally, that even the seismologists concerned are confident enough to venture predictions (though none so closely as 1982 ± 2 years). The latest of these professional forays into the fashionable field of earthquake prediction was published in *Nature* a few months ago and rules out the area between San Francisco and Parkfield for a really large earthquake before 1999, but accepts the possibility of a moderately large disturbance from 1981 onwards. Those predictions were based on recent observations of the rate of change of P-wave velocities, on which readers are brought up to date in an appendix to *The Jupiter Effect* (a title which neatly fits a book that unashamedly and provocatively attempts a geophysical explanation for the predictions of astrologers). Gribbin and Plagemann did not have time to fit this more recent work into their jigsaw and, in any case, they persuade us by other published evidence that the area on the San Andreas which is primed for triggering lies nearer to Los Angeles, south-east of Parkfield.

Even if such forecasts turn out to be less precise than hoped for, there is little doubt that California, as well as other thickly populated seismic areas, will suffer from great earthquakes which cannot be avoided unless lubrication can be applied to smooth the rate of release of stored energy. And as it would be a very brave (or ill judged) decision to pump water along the San Andreas Fault, the authors return to the unglamorous duty of spelling out the precautions which town planners and individuals can take to mitigate the inevitable effects. That their common sense statements of the obvious are considered worth printing demonstrates the social nature of the problem. The most sophisticated of observational and analytical efforts will contribute nothing to ease the disaster confronting a dam which, on the face of it, is intended to staple the edges of the Pacific and North American plates.

H. I. S. Thirlaway

as previously thought, a more or less accessory effect of extracellular secretion. Endolithic cyanophytes may even turn out to be 'rock-eaters' in the true sense.

Scanning electron microscope (SEM) studies of borings of a filamentous blue-green alga of the *Hormatonema* form[1-3] revealed the marks of a precisely controlled excavating process, suggesting the existence of specialised boring organelles in the alga (Fig. 1). Indeed, the discovery in the cyanophytes of very refined adaptations to an endolithic mode of life should hardly be a surprising find, since these organisms, according to palaeontological data, have been boring into calcareous substrates at least since the early Ordovician (that is, for about 500 Myr) and perhaps much longer than that[4,5].

The boring mechanism of endolithic algae has previously been described as an extracellular dissolution process: acid or chelating fluids, released by the terminal cell, supposedly dissolve small volumes of the mineral substrate and the algal filament penetrates step by step into a tunnel formed by a sequence of small hollows[3,6]. How the fluids are removed from the inner end of the inhabited tunnel, whether by extracellular circulation/diffusion or by metabolic uptake and intracellular transport, is not known. In the dissolution process, the micromorphology of the excavated space is determined by the solubility characteristics of the bored substrate and is thus beyond the immediate control of the organism. For example, the void space in bored calcite spar replicates the calcite rhomb[6], and borings in dolomitic limestone may contain residual crystals of poorly soluble dolomite which has resisted the attack[7].

The material described here derives from saline rock pools in the upper swash zone in modern beachrock west of Stazousa Point on the northern coast of Cyprus (see ref. 8). The bored rock consists in part of a coarse crystalline limestone, with optically uniform calcite crystals, several hundred micrometres across. These crystals provide excellent substrates for the study of algal borings by means of SEM.

The endolithic algae consist of dark blue filaments, about 300 μm long and 10 μm in diameter. Exposed to acid solutions the dark blue pigment turns reddish-brown, a reaction considered typical in *Hormatonema*[3,6]. In isolated colonies consisting of a few filaments, the algae grow radically away from a common starting point whereas in crowded colonies parallel filaments grow perpendicular to the rock surface. These arrangements are consistent with the observation that algal filaments commonly repel each other and avoid connecting with other tunnels[9].

The cavity formed by an individual filament is a fairly straight tunnel, replicating the organism. Branching of tunnels has not been observed.

As reconstructed from the microtopography of the tunnel walls, the boring process proceeds through the etching out of small grooves, about 1 μm in width and depth and 10 μm in length (Fig. 1). The wall relief increases slightly behind the terminal cell. The orientation of the grooves is approximately at right angles to the long axis of the tunnel. Interestingly enough, there are two laterally opposite sets of grooves, meeting in a zone of small pyramids. The arrangement indicates a bilateral symmetry in the boring apparatus.

The pattern of grooves shows no relationship to the internal ultrastructure or to the crystallographic parameters of the bored substrate. For example, where several tunnels run at different angles within a single calcite crystal, each tunnel has its own set of grooves which are perpendicular to the tunnel axis and are not related to the crystallographic structures of the continuous calcite lattice.

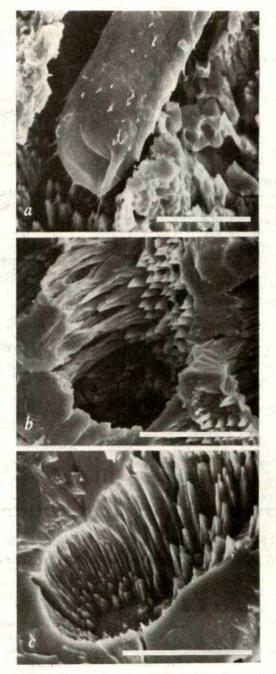
The bored rock material was collected for geological purposes and the samples were only rinsed in distilled water and air dried. Because of this crude treatment, the material


Fig. 1 Cyanophyte borings in calcite: SEM micrographs of fractured material. *a*, Penetrating tip of algal filament, slightly withdrawn from the inner end of the tunnel by shrinkage during preparation (note threads on the filament surface); *b*, oblique fracture cutting four algal tunnels in homogeneous calcite, showing one side of the bilateral pattern of grooves and the zone of small pyramids; *c*, inner end of algal tunnel with grooves and pyramids. Scale bars 10 μm.

is not suitable for a study of soft tissues, and the marks of the boring process cannot be related to specific parts of the algae. Complete algal cells, about 15 μm long and 10 μm in diameter, can obviously be ruled out as direct operators, but identification of possible boring organelles must await properly fixed and dehydrated algal material.

It is, however, interesting to observe that even in this poorly preserved material the algal filaments have a sparse coat of small threads, about 0.2 μm in diameter and 2–6 μm long (Fig. 1a). Similar threads have not been noted in the rich assemblages of endolithic algal filaments found in marine calcareous sediment grains[6,9-12]. Although there is

no real evidence to suggest that the threads are boring apparatus, their presence here is probably significant.

Three conclusions can be drawn from the micromorphology of the borings. First, excavation is a chemical process, but is not straightforward extracellular dissolution on a whole-cell scale. Second external organelles, about 1 μm wide and 10 μm long, are the immediate operators. Third, the boring apparatus has a bilateral symmetry.

It can be added that, although this article considers a single species of *Hormatonema* at one locality only, I have observed similar borings in the course of SEM analyses of sedimentary carbonates from the North Sea and the Baltic Sea. It seems probable that the described mode of boring is common in the cyanophytes.

This work is part of a Marine Carbonates Programme supported by grants from the Swedish Natural Science Research Council, the Swedish Royal Academy of Science through the Hierta-Retzius Foundation, and the Magn. Bergvall Foundation.

Correlation between selenium and mercury in man following exposure to inorganic mercury

THE ability of selenium compounds to modify profoundly the toxicity of both organic and inorganic mercury compounds has been demonstrated in experimental animals by Parizek and co-workers[1,2]. The analytical data of Ganther *et al.*[3] on tuna and of Koeman *et al.*[4] on marine mammals showed that natural levels of mercury and selenium are strongly correlated. Here we report an approximately molar ratio for these elements in certain human organs following exposure to high levels of inorganic mercury.

Mercury in post-mortem samples from three groups of people —workers in the mercury mine at Idrija, Slovenia, inhabitants of the town of Idrija and a control group with no known exposure—has been analysed over the past three years[5,6]. The study has been extended to include selenium. Although we do

not intend to discuss the mercury levels in detail, some interesting findings emerged (Table 1). Notably, the high accumulation and retention of mercury in the thyroid and pituitary; in the miners increases are of the order of a thousandfold, and in the population group about tenfold, relative to the controls. The kidney has previously been considered to be the prime accumulator of inorganic mercury, but in all eight mine workers, it ranked only third. Seven of them had been in retirement for periods up to 16 yr before death (see legend to Table 2), yet the pattern of distribution was essentially similar. It is clear that the retention of mercury in the organs with the highest accumulated levels, namely, thyroid, pituitary, kidney and brain, is very great.

In more recent post-mortem samples we have analysed both selenium and mercury to find a possible relationship between these elements in exposed humans. Both elements were analysed simultaneously by neutron activation from the same sample aliquot, using a volatilisation technique[7] modified to allow separation and measurement of both mercury and selenium[8]. The results to date are shown in Table 2, and clearly demonstrate an approximately 1:1 molar ratio for those organs which accumulate and retain mercury strongly, namely, thyroid, pituitary, and kidney. The same effect is also seen in brain samples (Table 3), with different sections of the same brain all displaying a near molar ratio. Since selenium, as an essential trace element, will normally be present in at least typical physiological levels, whereas mercury in non-exposed persons should only approach insignificant amounts, a molar ratio will only be observed for rather elevated values. Even slightly increased mercury levels, however, seem capable of raising the selenium content; the ratio of the increments over normal levels approaches the molar ratio in many cases.

The correlation coefficient *r* between mercury and selenium in the organ group thyroid, pituitary, kidney and brain (subject T.A.) from the miners is 0.998, with two virtually identical regression equations (*r* very nearly unity) of the form

$$(\text{Se})\text{p.p.m.} = 0.41(\text{Hg})\text{p.p.m.} + 0.21 \ \text{p.p.m.}$$

In molar terms, the ratio Hg–Se is 0.96:1. This ratio in the liver of marine mammals[4] was near 1:1 in molar terms over a 2.5 decade mercury concentration range, but only a small fraction of the mercury could be recovered as methylmercury. In our work, methylmercury levels in the exposed groups, as determined by an isothermal distillation and gas chromatographic method[9], were unremarkable, exceeding normal values only slightly. This also confirms the absence of any significant *in vivo* methylation in man.

The 1:1 molar ratio naturally suggests a direct Hg–Se linkage, though at this stage we can only speculate about the nature of the group or complex and its mode of attachment. Keeping in mind that the time between death and termination of exposure in the professionally exposed subjects varied greatly, it seems that the effect is both accumulative (as in the case of marine mammals and tuna) and retentive. This emphasises the strength of the Hg–Se interaction and suggests their removal from biological turnover. The coaccumulation of selenium observed in this study is certainly not the result of coexisting high levels of

selenium in the mine environment, as analysis of dusts and soils showed low values (around 1 p.p.m.) compared with mercury which is in the 100 p.p.m. range. In marine mammals and tuna the diet is much more enriched in selenium relative to mercury.

Thus in general it seems that the effect can occur where mercury is present as the methyl (tuna) or the inorganic form (marine mammals and man), and whether selenium is relatively abundant in the diet or not. The protective effect of selenium in animals has been shown for various forms of mercury[1,2]. It may be therefore that the coaccumulation of selenium is a natural or autoprotective effect. In this context it is interesting to note that possible preventive and therapeutic uses of selenium against mercury intoxication have been discussed by Parizek[1,2]. Certainly, the detailed metabolic, dynamic and structural mechanisms of this phenomenon seem worthy of further intensive study, in view of its toxicological implications and relevance to the metabolic role of selenium.

We thank the Boris Kidrič Fund of Slovenia and the US Department of Agriculture for financial assistance. We are also indebted to the staffs of the Institute of Pathology in Ljubljana and of the Idrija Mercury Mine for their cooperation.

Genetic analysis of behavioural responses to novelty in mice

To trace the genetic determinants of exploratory behaviour in house mice, I started a programme of selective breeding[1]. Using the F_2 generation from a cross between the inbred strains C57BL/6J and DBA/2J as the foundation population, male mice were selected bidirectionally for frequency of exploratory rearing responses displayed in a novel environment. To transfer alleles responsible for high rearing scores from the C57BL strain to the DBA genetic background, selection was combined with repeated backcrossing to DBA females over five consecutive generations. A comparable procedure has been used by Chai[2] for body size in mice. Since these early stages of the selection aimed at developing two lines of mice with similar genetic backgrounds, but differing for loci affecting rearing behaviour, no unselected control line was bred; the DBA strain could serve as this.

In the next stages, selection was continued with concomitant inbreeding by sib-mating to fix the relevant alleles within the two lines. Replicate selected lines[3,4] were not bred. This does not seem too serious a drawback because the purpose of the experiment was to identify individual polygenes controlling exploratory behaviour and the physiological mechanisms through which they act, not to study the potential response to selection *per se*. In the course of this breeding process, a number of the relevant alleles may not be maintained in the lines because of genetic drift (see also Schlager[5], who selected mice for blood pressure level).

After more than twenty generations of inbreeding, the lines, symbolised SRH (high) and SRL (low), must now be close to

*For rearing, 25; for locomotion, 50.
†$F_2 + B_1 + B_2$.

complete homozygosity and they are still clearly different for rearing score. This is really a difference in the response to novelty, since in a separate experiment with 44 SRH and 46 SRL mice we failed to find any differences between the lines for various exploratory activities carried out in the home cage. The lines seem to differ also for locomotor activity measured in a novel environment[1].

To estimate the number of loci contributing to these behavioural differences, intercrosses (F_1 and F_2) and backcrosses (B_1 and B_2) were made with the two selected lines. This report deals with the results of the analysis of these hybrid types, applying in the first instance methods that have been used with behavioural phenotypes such as susceptibility to audiogenic seizures[6], vocalisation[7], taste sensitivity to PTC[8], saccharin preference[9], and passive-avoidance performance[10] of mice. Single-locus inheritance was indicated and, to confirm this, the next step was a biometrical genetic analysis according to methods described[3-5,11]. The relationship between rearing frequency and locomotor activity was also considered.

Female mice from the SRH strain (20th generation; P_1) were mated with males from strain SRL (20th generation; P_2) to produce an F_1 population (no reciprocals), and the F_2, B_1, and B_2 populations were bred from F_1 females. All neonate animals were fostered to nursing mothers from a random-bred stock, in conditions described previously[1]. At the age of about 13 weeks, single male mice were placed for 15 min during the afternoon in a novel environment, an observation cage measuring $133 \times 53 \times 58$ cm and with a bedding of peat dust. The frequency of rearing responses (vertical activity) and the frequency with which animals intersected light beams activating photocells (horizontal activity) were recorded on counters. The numbers of subjects observed were 20 (P_1, P_2) and 30 (F_1, F_2, B_1, B_2).

The left-hand part of Table 1 shows the untransformed behavioural scores. The non-segregating populations differed from each other for rearing: there was a significant strain difference ($P < 0.001$; Mann–Whitney U test), whereas the F_1 took an intermediate position ($P < 0.03$ and 0.001, respectively). The latter was not true for locomotion; although the parental strains were clearly different ($P < 0.001$), the F_1 differed significantly from the P_1 only ($P < 0.001$) and it resembled the P_2. As far as the distribution of scores is concerned, particularly that of the B_2 suggested bimodality, indicating single-locus control of the behavioural differences. In particular with regard to rearing, the presumptively heterozygous animals within the pertinent populations seemed to have an optimum score (between 25 and 30). On the basis of the numbers of animals from the non-segregating groups that exceed an arbitrary critical score, we can calculate expected values for the segre-

gating populations and compare these with the observed numbers by means of χ-square tests for goodness of fit, as shown in the right-hand part of Table 1. The observed values did not deviate significantly from those expected and, thus, the hypotheses of monogenic inheritance of rearing frequency and of locomotor activity score are not rejected.

A biometrical genetic analysis was also performed; judged by the variances of the raw scores of the non-segregating P_1, P_2, and F_1 populations entered in Table 1, however, significant genotype–environment interactions were present, that is, Mather's second criterion was not fulfilled (F tests; for rearing: $P < 0.001$, 0.005, and 0.005; for locomotion: $P < 0.05$, 0.005, and 0.20). A square-root transformation proved unsatisfactory, but transformation to natural logarithms effectively eliminated the genotype–environment interactions (see Table 2). In these transformed data, significant strain differences were also found for rearing ($P < 0.001$; Student's t test) and locomotion ($P < 0.001$), and the F_1 was again intermediate for rearing ($P < 0.02$ and 0.001, respectively) but not for locomotion (significantly different from the P_1 only; $P < 0.001$). Application of scaling tests A, B, C, and D (Mather's first criterion) in Table 2 shows that the ln transformation rendered the scale of measurement adequate for rearing as well as locomotion, that is, any epistatic interactions were removed, as is also evident from the estimates of components [i], [j], and [l]. With regard to both behaviours, the additivity component [a] was significant and dominance [d] not significant. The heritability, calculated from the components of variation, differed from zero only for rearing (66%) and the minimum estimates of the number of effective loci yielded 0.71 and 0.58, respectively; these values are compatible with single-locus control. Some caution, however, is justified in view of the significant additivity components.

From the correlation coefficients in Table 3 it seems that rearing and locomotion are correlated, even more strongly in the segregating populations than in the non-segregating groups. Significant positive correlations were also established in most of the previous generations of the selection lines; it now seems highly improbable that these resulted from chance fixation of different genes. If traits vary dependently, as shown here for rearing and locomotion, the observed differences

must be the result of variation in the same genetic factor or factors. The locus which controls rearing frequency and the locus which influences locomotor activity may be identical (pleiotropy) or, perhaps, closely linked (gene block).

This report demonstrates that it is possible to single out by means of selective breeding one locus responsible for differences in a quantitative behavioural variable in mice, the reaction to novelty. Previous investigations with the anticholinergic drugs scopolamine and methylscopolamine provided evidence that the genetic factor acts through a hippocampal cholinergic mechanism which regulates exploratory tendencies[1]. The factor may be allelic with the gene *Exa* (for exploratory activity level; identified by using recombinant inbred strains), the action of which can be changed by another locus designated *Sco* (scopolamine-induced modification of exploratory activity[12]). Apart from the isolated gene, other allelic differences that were not maintained during the selection process may also have contributed to the behavioural difference between the ancestral strains.

'Lesbian' phenotype of *Drosophila melanogaster?*

A BEHAVIOURAL phenotype of female *Drosophila melanogaster* has been found which is characterised by the emission of what seems to be a somewhat rudimentary form of male courtship behaviour; it is directed towards other females, and also towards males. 'Lesbian' behaviour has not been reported before, although it may occur in other strains of *D. melanogaster*.

Female *D. melanogaster* do not usually seem to initiate courtships (although see ref. 1 for factors influencing their attractiveness to males), but take a somewhat passive role—unless they are unreceptive, when a repertoire of rejection responses comes into play[2]. The most important of these rejection behaviours is extrusion of the genitalia towards the courting male.

The courtship of the male has been described several times[3-5]: the male orientates to the female and vibrates one or both wings, producing a signal important in species recognition[6] and in the sexual stimulation of the female[7-9]. The male extends the proboscis and licks the genitalia of the female, at the same time flexing the abdomen in preparation for attempts at copulation. During this procedure the tarsal segments of the forelimbs, with the associated sex combs, are used to grasp the genital region of the female[10].

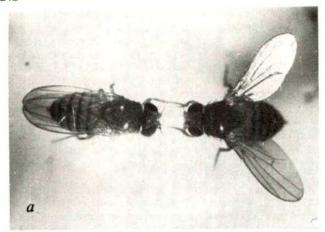
Females showing lesbian behaviour clearly demonstrate several of these male behaviours. The female orientates to and follows other females, sometimes engaging in a bout of foreleg tapping[3]. Head-on 'courtship' occurs with both wings extended, a relatively rare phenomenon even in males (Fig. 1 *b*). Most of the behaviour is, however, directed to the genitalia of the courted female (Fig 1 *a*), where following and wing extension commonly occur with the tarsi of the forelegs used in a behaviour similar to, but far less precise than, the grasping performed by males; in females it might be called groping. It is not yet known whether an acoustic signal is produced during wing extension, but this behaviour seems to be similar to, although of shorter duration than, the wing vibration of males. In lesbian females it often intergrades into the flicking behaviour[2] of both normal females and males.

Although this behaviour may be performed extremely vigorously, it is broken into discrete bouts of short duration, usually of less than 20 s (mean = 4.68 ± 0.33 s); such bouts may, however, follow one another in quick succession, and on occasions the behaviour becomes effectively continuous. Even in the individuals which show the behaviour most intensively I have not observed proboscis extension and licking of the genitalia; attempted copulation is also absent. A response to lesbian behaviour by sibling virgin females is extrusion of the genitalia; flicking also frequently occurs.

The observations were conducted on pairs of females placed at eclosion in cylindrical plastic cells (30 mm high, 22 mm in diameter), filled to within 1 cm of the top with food medium. Observations were made by repeated scanning of the sample of cells in the evening of days 2 and 3 after eclosion. A female was only classified as of lesbian phenotype when the behaviour had been observed more than once.

Lesbian behaviour has as yet only been found in a series of related 'balanced lethal' strains, designed to maintain the gene *Fs (2)B* (female sterile) in the heterozygous state. In the strain *Fes31*, for example, samples from four different generations gave a mean of 23.7 ± 4.0% females showing lesbian behaviour. The composition of *Fes31* with respect to chromosome II is:

$$fs\ dp^+\ Sp/al^2\ Cy\ (In2LR)\ cn^2\ L^4\ sp^2$$

Lesbian behaviour is not genetically dependent on any of these mutations on chromosome II, since the behaviour is easily retained when both chromosomes II are substituted for those of a laboratory strain in which lesbian behaviour has not been observed (Pacific and Novosibirsk strains).


The crossing carried out to transfer the factor(s) responsible for lesbian behaviour to a non-mutant genetical background, rearing in groups rather than single families, has provided the data shown in Table 1. This suggests that *Pacific* is genetically

Table 1 Preliminary genetic data on lesbian phenotype

10 *Fes31* (♀♀ showing lesbian behaviour) × 10 *Pacific* ♂♂

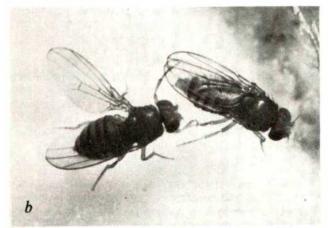
F_2	72	25	34.7


Fig. 1 *a* and *b*, 'Courtship' behaviour of lesbian phenotype females. × 12.

different to *Fes31* with respect to the factor(s) controlling lesbian behaviour, with the *Pacific* allele(s) showing incomplete dominance. Conclusions as to the mode of inheritance of this behaviour must await further genetical and behavioural studies.

Analysis of the data gained from the observations described above shows that lesbian females are found together more frequently than would be expected by assuming a random distribution of such females across the cells (Table 2). In all cases the observed frequencies differ with the same pattern from those expected. It is thus possible that lesbian females mutually stimulate each other into manifestation of lesbian behaviour. This implies that some potentially lesbian females are not detected by the measuring procedure used and that this is therefore an underestimate of the proportion of such females in the sample.

Although this behavioural phenotype closely resembles certain aspects of male courtship behaviour it cannot yet be definitely asserted that it derives from this system. It may, for example, have evolved to serve a function of 'spacing' or 'aggression' between females, or as a response to the abnormal conditions imposed by the mutations of the balanced lethal system.

Whatever its function and origins may prove to be, lesbian behaviour is an item in the (expanding) repertoire of *D. melano gaster* (see for example the 'homosexual' mutant of Gill[11]), on which genetical techniques of analysis may be brought to bear. More detailed behavioural and genetical studies are at present under way.

I thank Dr G. Pasteur and Professor A. Manning for discussions, and the SRC for a NATO Science Research Fellowship.

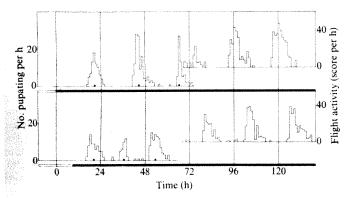
Entrainment of the pupation and adult activity rhythms during development in the mosquito *Anopheles gambiae*

PREVIOUS work on the initiation of the pupation and flight activity rhythms in mosquitoes[1-3], has been interpreted[4] as showing that there is an ontogenetic distinction between the 'clocks' controlling development and adult behaviour. Results with *Aedes taeniorhynchus*[1,2] suggest that the developmental clock stops after controlling the time of pupation and that the adult behavioural clock does not start until some time after emergence. In *Culex pipiens pallens* the adult clock seems to start just before adult emergence. By contrast, the results reported here indicate that in the mosquito *Anopheles* (*Cellia*) *gambiae* Giles, the flight activity rhythm can be entrained during development at least as early as the second larval stage. The same *Zeitgeber* also sets the phase of the pupation rhythm.


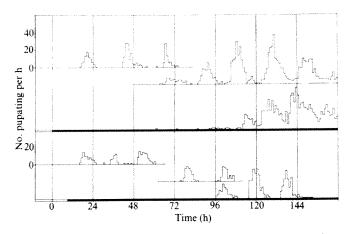
The insects used were *A. gambiae* species A from a culture originating in Pala, Upper Volta. They were reared in LD 12:12 (alternating 12 h light: 12 h dark; 300 lx) and then placed in DD (constant dark) either at the normal time of light-off or after prolonging the light period. Similar experiments with the adults have shown that prolonging the light period resets the flight activity rhythm[5]. In the present experiments 20–40 adults emerged into a muslin cage (30 mm cube) and the total flight activity was monitored using the acoustic actograph technique[6,7]; as in previous exper

ments, a score of 1 was given for any flight activity in any minute. The temperature was maintained at 27 °C.

In the first series of experiments, the change to DD was made during the pupal stage. In an LD 12:12 regime, pupation takes place mainly in the last 6–9 h of the light period, reaching a peak 3–4 h before the end of the light phase. In each experiment, 30–40 pupae, which had pupated between 3.5 and 4.5 h before the normal end of the light phase, were given the final 'light-off' either at the normal time (in this case about 4 h after pupation) or after an extra 12 h of light. In all experiments there was a clear cycle of adult activity which was in phase with the time of the final light-off; the period of the cycle was about 23 h as in previous flight activity experiments[5]. During this series of experiments, adult emergence was monitored under infrared illumination (continued throughout the dark period) using an infrared sensitive TV camera (Link 101S)[x]. The adults emerged 26–30 h after pupation and the time of emergence did not seem to be affected by the difference in the time of light-off. This is consistent with Nayar's observation[1] that the time of emergence in *Ae. taeniorhynchus* is dependent on the pupation rhythm, the duration of the pupal stage being determined mainly by temperature.

In a second series of experiments, the change to DD was made during the larval stage. Figure 1 shows the flight activity of the adults when the change was made during the fourth (final) larval stage and also the timing of pupation in a parallel series of experiments in which mixtures of third and fourth stage larvae were put into constant dim red light. In both series of experiments the change was made either at the normal time of light-off or after prolonging the final light period for 9 h. In the pupation experiments, the pupae were collected from the larval bowls at hourly intervals. In DD (dim red light) there is a cycle of pupation with a period of just under 24 h. Prolonging the final light period does not affect the timing of the first peak, but resetting is complete by the third peak, which seems to correspond to the second peak after light-off at the normal time. Between these two peaks is another smaller peak; this may consist of those individuals which were sufficiently advanced to pupate towards the end of the first reset 'gate'. These results suggest that, if the clock is reset immediately by the extra light, the contribution of the clock to the timing of pupation must take place 24–30 h before pupation actually occurs.

The rhythm of flight activity does not seem to be affected by the actual time of pupation. The flight activity (in DD) of adults derived from pupae selected from these pupation experiments shows that the rhythm is reset by prolonging the final light period, even in individuals which pupate in

Fig. 2 Timing of pupation when the change to DD was made with batches of larvae of different ages.


the first peak, in which the time of pupation has been unaffected by the extra light.

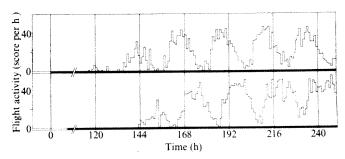
Experiments in which the change to DD was made at an increasingly early stage (Fig. 2), indicate that the period of the rhythm controlling pupation remains constant at about 24 h for four cycles and then decreases to 16–20 h. This change in period also occurs when the rhythm is reset by prolonging the final light period. Figure 3 shows the flight activity of mosquitoes which pupated in the peak approximately 90 h after light-off, when the change to DD was made with a mixture of second and third stage larvae. It can be seen that the activity is still cyclical, with a period of about 23 h, and that the phase is determined by the time of light-off. Despite the change in period of the pupation rhythm, mosquitoes which pupated 132 and 144 h after light-off still showed a clear cycle of flight activity, which, in period and phase, was completely consistent with that in Fig. 3.


Fig. 3 Flight activity of mosquitoes which pupated approximately 90 h after light-off.

Thus, there seems to be considerable overlap between the 'clocks' controlling the timing of pupation and adult activity and this is surprising in view of findings with other mosquitoes[2,3]. In *Drosophila*[6] the evidence implies that the same clock may 'gate' eclosion and control adult behaviour, persisting through development and metamorphosis. By contrast, in *A. gambiae*, the apparent acceleration of the pupation rhythm, the persistence and stability of the flight activity rhythm and the altering phase relation between the two rhythms suggest that we are dealing with two distinct timing processes. If this is so, the function of the early occurrence of the flight-activity rhythm during development remains a puzzle. Possibly it may play some part in the control of larval or pupal activity.

Fig. 1 Pupation and subsequent adult flight activity after a change to DD late in the larval stage, either at the normal time of light-off or 9 h later. ●, Median of pupation peak.

Chemotaxis of the spermatozoa of *Ciona intestinalis*

CHEMOTAXIS of animal sperm, long thought not to occur[1-4], was first proved in the marine coelenterate *Campanularia*[5], and since then has been observed in other hydroids[6,8]. The species-specificities and cross reactions between sperm and reproductive structures of these species and genera have been described[6], and some of the attractants have been isolated and their chemical properties reported[7]. In spite of circumstantial evidence for sperm chemotaxis in other phyla[13,14] the sperm behaviour leading to aggregation has not been described. I now report evidence of sperm chemotaxis to egg water and egg extracts (see Table 1 for details) of *Ciona intestinalis* (Protochordata: Urochordata), a primitive chordate. These results imply that sperm chemotaxis either has evolved independently in groups widely separate on the phylogenetic scale or is widespread in the animal kingdom.

Minganti[10] reported species-specificity of the sperm activation and agglutination responses to egg water in five species of Mediterranean tunicates, including *Ciona*. My own observations of *Ciona* sperm in the vicinity of unfertilised eggs indicated that the eggs, or a preparation of egg water (Table 1), activated nearby non-motile spermatozoa[10,11] and seemed to induce turning movements[11]. To investigate whether these turns were chemotactic, *Ciona* gametes were obtained by dissection or by shedding the animals[12] and the methods of observation and photographic techniques previously used on hydroid sperm[5,9] were applied.

Figure 1a shows a typical preparation of *Ciona* sperm swimming against an albumin-coated glass microscope slide under dark field illumination. The cells were describing circles of either 200–250 nm or 100–120 nm diameter. Some cells switched from one diameter to another and often made short, straight deviations shifting the circle to a new position (not shown). In fresh suspensions the diameter of the circle was much larger and some cells followed long, straight paths, possibly because they had not yet made proper contact with the slide surface. As the preparation aged, the straight trails were seen less often or not at all and the diameter of the circles decreased to about 100 nm. The tight circling behaviour sometimes led to the cell leaving the surface and swimming up into the medium.

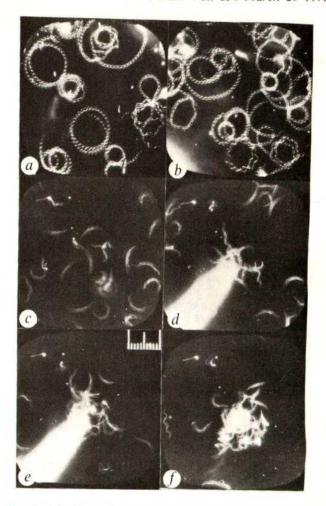
When seawater was injected from a pipette at the lower left as shown in Fig. 1b, sperm behaviour was basically unaltered. There was no sign of rheotaxis during the 1–2-s injection. When *Ciona* egg extract or egg water was injected (Fig. 1c–f) the cells aggregated rapidly at the pipette tip, sometimes even if no material was injected. After the pipette was removed the aggregate remained but tended to broaden with time. Figure 1f shows that the cells in the aggregate remained motile and did not agglutinate, though some stuck to the slide surface, particularly where the pipette had scraped away the albumin coating.


Fig. 1 Behaviour of *Ciona* sperm in the presence of seawater and egg extract injections. *a*, *Ciona* sperm swimming against a glass surface with a beat frequency of 40 Hz. Exposure was for 4 s and flash frequency was 20 Hz. *b*, Similar preparation with a pipette injecting seawater from the lower left, just off the field of view. Exposure was for 2 s and flash frequency was 20 Hz. *c*, Same as (*a*), 0.33 s exposure and flash frequency approximately 40 Hz. *d–f*, Same preparation as (*c*) with a pipette injecting *Ciona* egg extract (*d*, *e*) followed by its removal (*f*). Times between frames are: *c–d*, 2 s; *d–e–f*, 1 s each. The smallest scale division is 10 μm.

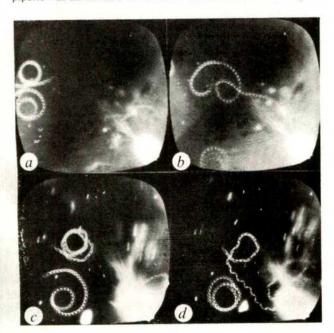
To observe the details of sperm behaviour as they entered the aggregation area, individual cells circling on the slide surface were exposed briefly to egg extract released from a nearby micropipette. Figure 2a and c shows the situation before the attractant reached the sperm and Fig. 2b and d shows sperm behaviour during the subsequent few seconds in two typical experiments. When the sperm perceived the attractant they stopped circling and moved rapidly toward the tip of the pipette. If the paths were not straight toward the tip, the cells reoriented by looping (Fig. 2b), by making a second direct turn (Fig. 2d) or by making minor adjustments in the path (Fig. 2b). These behaviours were not seen if seawater was injected in the same situation.

Not all the sperm responded to the attractant, the proportion of non-responders increasing with the age of the preparation. A flagellar beat frequency decrease from 38–41 Hz to 32–35 Hz was associated with loss of responsiveness. In contrast to *Tubularia* sperm[9], it has been difficult to identify a single characteristic flagellar response associated with turning. Furthermore, preliminary measurements indicate no marked increase in swimming velocity as the sperm moved towards the source of attractant in spite of small adjustments of beat frequency like that shown in Fig. 2d. This latter observation may, however, indicate merely that the sperm were already swimming at the maximum velocity possible.

Table 1 Specificity of urochordate sperm chemotaxis


Sperm type Egg extract (titre)	*Ciona*	*Styela plicata*	*Styela clava*	*Tubularia* (Hydrozoa)
Ciona (9)	+ (> 100)	− (10)	− (4)	− (5)
S. plicata (4)	− (10)	+ (8)	NT	− (2)
S. clava (0)	− (4)	NT	− (4)	NT
Tubularia (12)	− (5)	− (2)	− (2)	+ (> 100)

Numbers in parentheses in columns 2–5 indicate numbers of trials. +, Aggregation of motile sperm; NT, not tested. Egg water was prepared by placing several thousand prewashed eggs into 5 ml of seawater and leaving the preparation to stand for 3–5 h at room temperature. The medium was then drawn off the eggs and tested against fresh sperm. Eggs treated in this manner are fertilisable and develop into normal tadpoles. Egg extract was prepared by removing the seawater from several thousand eggs and replacing it with a small volume of 100% ethanol. After a suitable extraction period (30 min at room temperature) the alcohol was drawn off, evaporated to dryness and the residue was diluted into seawater for testing. One hundred *Ciona* eggs, extracted in 50 µl of ethanol, produced an active seawater solution which could be half-serially diluted eight or nine times before the attracting activity was lost (titre = 8–9). Five times this number of eggs of either species of *Styela*, extracted in the same manner, gave solutions with no activity against *Ciona* sperm. Follicle cells were isolated by passing eggs through a Pasteur pipette several times in calcium–magnesium-free seawater. The eggs were removed by low speed centrifugation (500 r.p.m.) and the follicle cells were collected at 2,000 r.p.m.

Although attractant activity can be obtained by alcoholic extraction of several tissues of adult *Ciona* (particularly those associated with the ovotestis) eggs consistently produced the highest titres. The distribution of attractant activity in adult tissues remains to be determined. Extracts of tissues from immature *Ciona* were inactive. Extracts of isolated outer egg follicle cells were very active and the eggs from which they had been removed remained active (see Table 1 for method). Since all the follicle cells could not be removed from the egg chorions, and since both egg and follicle cell preparations contained a clear, viscous mucus as a persistent contaminant, the exact source of the attractant remains in doubt.

The species-specificity of the response has been partially determined. Alcohol extracts of eggs of the tunicate *Styela plicata* obtained by light-induced shedding (C. Lambert, personal communication), had no effect on *Ciona* sperm, but they did attract sperm of *S. plicata*. Extracts of *Ciona* eggs of rather high titres (Table 1) had no effect on the sperm of *S. plicata*. No chemotaxis has been observed in the sperm of *Styela clava* toward any of the egg extracts used, even those prepared from eggs of this species. There is no cross reactivity between the sperm and sperm attractants of

Tubularia and *Ciona* (Table 1). Curiously, although *Ciona* is known to be largely self-sterile[13], egg extracts prepared from any one animal will attract sperm obtained from that same animal.

Observations that chemotaxis of the sperm of the hydroid *Hydractinia echinata* occurs to eggs of that species[11] have confirmed directly the ability of spawned eggs, free of complex outer investments, to attract spermatozoa species-specifically. *Ciona* also sheds its eggs before fertilisation, and though the egg bears a complex array of investing cells, it nevertheless produces a substance capable of attracting sperm species-specifically. Therefore, arguments[16,17] that fertilisation of animal eggs in an aqueous medium occurs as the result of chance encounters with sperm may have to be re-evaluated. A possible advantage of sperm chemotaxis to spawned eggs comes from the effective increase in volume of the egg as a target for the sperm. Its further role in animal fertilisation remains to be determined.

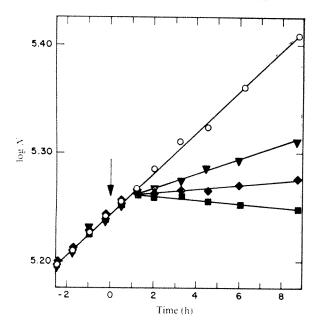
Fig. 2 Sperm attraction by *Ciona* egg extract. *a* and *c*, Two cells circling on a glass slide close to a pipette injecting egg extract (beat frequency approximately 40 Hz). Exposure: *a*, 2.5 s; *c*, 1.5 s; flash frequency was 17 Hz. *b* and *d*, Less than 1 s later. Exposure: *b*, 3 s; *d*, 2.25 s; flash frequency was 17 Hz. *b*, Response of the lower of the two cells in (*a*). The change in beat frequency for the upper cell in (*d*) as it approached the pipette was an increase of about 1.5 Hz. Same scale as in Fig. 1.

Different drugs arrest cells at a number of distinct stages in G₂


SEVERAL physical and chemical agents can induce susceptible mammalian cell populations to accumulate in the G_2 phase of the cell cycle[1-8]. The question arises whether cells treated with different agents all accumulate at a single 'restriction' stage within G_2 or, alternatively, stop at a variety of stages.

Techniques of cell-cycle analysis can show the precise

stage at which cycle progression capacity is lost in cells treated with inhibitory substances. If a drug is added to an exponentially growing culture, the time between addition and change in growth rate determines the time in the cell cycle preceding division—the M/G_1 boundary—at which the agent inhibited progression[9]. Cells at a stage beyond this temporal marker at the time of addition continue through the cycle and divide, while those at earlier stages are prevented from progressing at the normal rate. The time is calculated back from M/G_1, since division is the parameter measured.

To determine the precise stage in G_2 that selected chemotherapeutic agents stopped cell-cycle progression, I measured the concentration of cells in exponentially growing cultures of CHO Chinese hamster cells at different times before and after addition of drugs. Figure 1 shows data obtained by treating cells with various concentrations of neocarzinostatin, a compound effective against human leukaemias[10]. Although the exact mode of action for this drug is unknown, neocarzinostatin apparently interacts with the DNA, causing a change in DNA structure[11]. The cells continued dividing at the exponential growth rate (culture doubling time of 16.5 h) for 60 min after addition of the drug; thereafter, in cultures receiving large concentrations of the drug, there was no further increase in cell number, and there was even an indication of a slight loss in the number of cells. With lower concentrations, where the cell cycle was incompletely inhibited, the rate of increase in cell number was decreased, commencing 60 min after addition of drug. Although the rate of progression for affected cells was different at the three drug concentrations, a value of 60 min was obtained in all three cultures for the time interval between addition of the drug and change in the rate of division. Therefore, with a wide (20-fold) range of drug concentrations, the terminal point of action of neocarzinostatin within G_2 appeared to be independent of concentration. (A similar effect was obtained with the other agents studied.) Continued incubation of these cultures for 36 h, in the presence or absence of drug (that is, cells resuspended in drug-free medium after treatment with neo-

Fig. 1 Determination of the terminal point of action of neocarzinostatin in line CHO Chinese hamster cells. A culture of exponentially growing CHO cells in F-10 medium, supplemented with 10% calf serum and 5% foetal calf serum, was split into four subcultures. At time zero, one culture received no drug and served as the control (○). Neocarzinostatin was added to the other cultures, yielding final concentrations of 50 µg ml⁻¹ (▲), 400 µg ml⁻¹ (◆), or 1,000 µg ml⁻¹ (■). Cells were counted at hourly intervals with an electronic cell counter.
Fig. 2 Drug-specific arrest of progression at different stages within the G_2 phase of the cell cycle in asynchronous cultures of CHO cells. The terminal point of action was determined as in Fig. 1 for the following agents: CLZ, chlorozotocin, NSC No. 178248; STZ, streptozotocin, NSC No. 85998; AMD, actinomycin D, NSC No. 3053; MNU, 1-*trans*-(2-chloroethyl)-3-(4-methylcyclohexyl)-1-nitrosourea (Me-CCNU), NSC No. 95441; BLM, bleomycin, NSC No. 125066; CNU, 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea (CCNU), NSC No. 79037; BNU, 1,3-*bis*-(2-chloroethyl)-1-nitrosourea (BCNU), NSC No. 409962; NCS, neocarzinostatin, NSC No. 69856; CHM, cycloheximide, NSC No. 185; and PUR, puromycin, NSC No. 3055. Drugs were obtained through Drug Research and Development, Division of Cancer Treatment, National Cancer Institute. The drug solutions were prepared immediately before use. The terminal point of action for each agent was determined in multiple cultures using 20–80-fold concentration ranges for each drug.

carzinostatin for 1 h), resulted in populations comprised almost entirely of cells in G_2, based on measurements of population DNA content obtained with the Los Alamos flow microfluorometer[8]. Thus, there was a net increase in cells in G_2, indicating that the cells initially in late G_2, M, G_1 or S could reach G_2, but no further. Some irreversible change occurred in response to treatment with neocarzinostatin that predisposed the cells to stop in G_2, regardless of the stage of the cell cycle in which they resided while exposed to the drug.

In similar fashion, the terminal point of action was determined for various drugs which cause cells to accumulate in G_2, as shown in Fig. 2[8,12,13]. The agents tested caused the cells to stop in different portions of G_2. Thus, at least in so far as the agents studied are concerned, cells do not stop at a single stage within G_2. Rather, the data seem to agree well with the model proposed by Mitchison[14] for multiple transition points within G_2.

With the exception of the protein synthesis inhibitors (puromycin and cycloheximide), all agents tested caused at least a partial enrichment in the fraction of cells in G_2, similar to the effects of neocarzinostatin. Although accumulation of cells in G_2 was possible with these agents, the effects on progression capacity were not readily reversible, so that none of these agents seem to be useful in preparing synchronised populations for study of late interphase events.

I have not devised a testable model to encompass all the observations reported here. The well documented arrest of mammalian cells in G_2 after X-irradiation, however, shares many features with the results presented here[1–4]. Perhaps the consequences to the genome of X-irradiation and treatment with these agents are similar in mammalian cells[15,16], although the actual biochemical mechanisms may be different.

I should like to hypothesise that a surveillance mechanism operates throughout G_2 to eliminate from the proliferative mode cells with altered DNA. Such a surveillance mechanism would examine cells at multiple stages within G_2 to ensure that either the damaged DNA was repaired normally, in which case a cell would be returned to cycle, or an unrepaired cell would be converted to a non-viable state, even though several abortive rounds of division might occur before cell death. (From an evolutionary standpoint, conversion to a nonviable state would limit the dissemination of grossly deranged mutant cells and would decrease the frequency of survival of the damaged cell in competing with normal cells for essential nutrients.) Thus, in this model, G_2 would represent a crucial period during which an essential decision is made concerning further cellular proliferation. This model does not exclude the possibility that

additional proliferation decisions could be made in other portions of the cell cycle.

The hypothetical surveillance mechanism is not foolproof, since viable mutants have been isolated from mammalian cell lines[17,18]. Of course, a totally foolproof mechanism would preclude even evolutionary changes. I feel that drugs such as we used may provide valuable probes for future studies of proliferation control mechanisms.

This study was supported by a contract from the National Cancer Institute, under interagency agreement with the US Atomic Energy Commission.

Induced agglutinability of 3T3 mouse fibroblasts

CONCANAVALIN A (con A) preferentially agglutinates polyoma virus-transformed 3T3 cells (Py3T3) compared with 3T3 cells[1]. Brief proteolytic treatment of 3T3 cells results in agglutinability comparable with that of Py3T3 cells, and this is consistent with the suggestion that constraints at the 3T3 cell surface prevent migration and clustering of con A receptors[1-3]. We now report that 3T3 cells are as equally agglutinable as Py3T3 cells after a brief exposure to low ionic strength conditions (LIS, isosmotic). The data suggest that the mobility of con A receptors is altered by electrostatic interactions at the cell surface.

Py3T3 and 3T3 cells were cultured on plastic substrate at 37 °C, pH 7.0, in Dulbecco's modification of Eagle's MEM, supplemented with 10% foetal calf serum and antibiotics (Grand Island Biological Co.). Preliminary experiments showed that agglutination by con A was a function of time, pH, con A concentration, cell density and oscillations per min for the reaction vessels[4]. Osmolarity was maintained at 340 mosmol for all assays using D-mannitol, which does not inhibit con A binding[5]. Hapten-inhibition with α-methyl-D-mannoside was used to confirm con A specificity. The con A was grade III, twice crystallised (Sigma).

Some properties of Py3T3 and 3T3 cells, determined in this laboratory are shown in Table 1. Half-maximal agglutination (HMA, defined as the concentration of con A required to agglutinate 75% of the cells) was 650 µg ml^{-1} for 3T3 cells compared with 75 µg ml^{-1} for Py3T3, when assayed at regular ionic strength (RIS, 150 mM). Prior incubation of 3T3 cells for 30 min at LIS in the presence of con A increased the agglutinability considerably (Fig. 1). The HMA was shifted to 75 µg ml^{-1}, and the concentration dependence was similar to that observed for Py3T3 cells at RIS. This

Table 1 Properties of mouse fibroblast lines used

	3T3	Py3T3
Generation time (h)	23.5 ± 0.1	29.1 ± 0.6
Saturation density (cells cm^{-2})	6.4×10^4	86.0×10^4
Transplantability	Negative	Positive
Agglutinability (HMA)		
RIS (150 mM)	650	75
LIS (< 50 mM)	75	75

Transplantability was tested by injecting 20 Swiss albino mice (immunosuppressed using 450 rad, whole body) with 10^7 viable cells from logarithmic-phase cultures. Py3T3 cells caused progressive tumour growth in 17 out of 20 mice, compared with 0 out of 20 when injected with 3T3 cells. All agglutination assays used 5×10^5 cells per ml, collected from log-phase cultures, rinsed twice with phosphate-buffered saline (PBS) containing 5 mM EDTA, followed by suspension in PBS containing 10 mM CaCl$_2$. Con A was added using constant volumes, 0.5 ml cells and 0.5 ml con A, incubated for 30 min at 37 °C, and 125 Hz min^{-1}. HMA is defined as the concentration of con A (µg ml^{-1}) required to agglutinate 75% of the cells. LIS condition was a 30 min incubation before addition of con A. Control agglutination (no con A) did not exceed 10%. Percentage of cells agglutinated was calculated by multiplying average clump size by number of clumps compared with free cells.

enhanced agglutination was observed once the ionic strength was below 50 mM (Fig. 2).

The following properties of this induced agglutinability were demonstrated in parallel experiments: (a) enhanced agglutination was only observed when con A was present with the cells at LIS, that is, incubation at LIS without con A, followed by addition of con A and assay at RIS did not enhance agglutination; (b) once cells were incubated with con A at LIS, agglutinability was enhanced when assayed either at LIS or RIS and (c) the LIS effect was not altered by removal of sodium, potassium or chloride ions (shown by holding the ionic strength constant using other monovalent salts).

Table 2 summarises the nature of the LIS effect with an attached cell preparation using human erythrocytes[6]. The LIS effect was temperature-sensitive, con A-specific, blocked by prior fixation of the cell membrane and not affected by inhibitors of metabolic energy.

These data demonstrate the importance of the ionic environment at the cell surface in determining agglutinability. The enhanced agglutination of 3T3 cells at LIS was phenomenologically identical to the agglutination of Py3T3 cells at RIS by the following criteria: (a) the LIS effect was abrogated using an inhibitor of con A binding; (b) the effect was temperature-sensitive and unaffected by inhibitors of metabolic energy; (c) the HMA was the same value at LIS

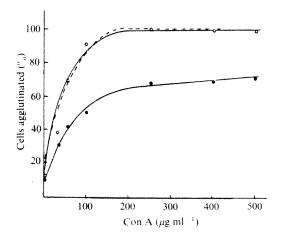
Fig. 1 The concentration dependence of agglutination with con A is shown for Py3T3 cells at RIS (150 mM) (– – – –); 3T3 cells at RIS (●); and 3T3 cells at LIS (< 50 mM) (○). Agglutination assays performed as described in Table 1 and values represent the means of triplicate determinations.


Table 2 Effect of various treatments on enhanced agglutinability of 3T3 cells at LIS

Treatment	Effect on agglutination
37 °C	Enhanced agglutination
25 °C	Enhanced agglutination
4 °C	No agglutination
Formalin (10%, 30 min)	No agglutination
Glutaradehyde (2.5%, 30 min)	No agglutination
2,4-Dinitrophenol (10 mM)	Enhanced agglutination
Sodium azide (10 mM)	Enhanced agglutination
Potassium cyanide (10 mM)	Enhanced agglutination
α-Methyl-D-mannoside (50 mM)	No agglutination

Cultures were rinsed with PBS, pH 7.2, and incubated at LIS with 340 mM D-mannitol, buffered to pH 7.0 with 10^{-5} M phosphate. Haemadsorption assay used human type O erythrocytes[12] layered over the attached cells at a 1% concentration for 30 min, then removed by gentle rinsing with PBS. Results shown above used monolayer 3T3 cells treated with con A (50 μg ml^{-1}) after the indicated cell treatment. Enhanced agglutination indicates heavy clusters (> 10 per cell) of erythrocytes attached to 3T3 cells; no agglutination indicates background adsorption (0–3 per cell). Similar results were obtained using erythrocytes treated with con A, then assayed against untreated 3T3 cells.

for 3T3 cells as observed for Py3T3 cells at RIS and had the same concentration dependence, and (d) it was not necessary to digest the cell membrane with proteolytic enzymes to enhance agglutinability.

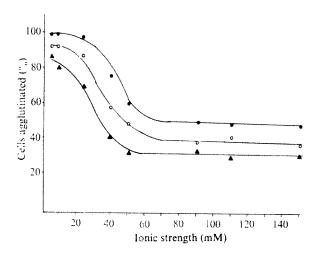
The above observations are consistent with the following concept of electrostatic interactions at the cell surface on addition of con A. Lipid bilayers are sensitive to the ionic environment[7,8], and binding con A results in an increased surface charge density[9]. Sufficient instability of lipid may require the reorganisation of lipid structure (to maximise order and decrease surface charge density) resulting in the


Fig. 2 Agglutination of 3T3 cells as a function of ionic strength. Con A at 200 μg ml^{-1} (●), 100 μg ml^{-1} (○), and 50 μg ml^{-1} (▲).

migration and clustering of con A receptors. Clustered binding sites could be stabilised due to cross-linking by con A. The threshold for lipid instability is considered low for 3T3 cells compared with Py3T3 cells since the membrane lipid is inherently more fluid in the transformed cell[10]. A low threshold for 3T3 cells is obtained by incubation at LIS, which increases the surface charge density[11], and addition of con A causes threshold instability resulting in the clustering of con A receptors. Although other possibilities exist, the concept of a threshold electrostatic condition for the instability of membrane lipid is consistent with the inherent

differences in agglutinability of Py3T3 and 3T3 cells, and enhanced agglutination at LIS.

Growth-enhancing protein obtained from cell surface of cultured fibroblasts

NORMAL animal cells do not grow at extremely low cell density under ordinary culture conditions[1,2]. This property of population dependence on cell proliferation has long been a crucial disadvantage for establishing clonal cultures of animal cells. Feeder layers or conditioned media are therefore used to sustain the growth of single cells in culture. The growth-enhancing material in conditioned media, the conditioning factor, is thought to be a large aggregate of macromolecules of pericellular environment[2]. This assumption was confirmed by the findings that cultured chick embryo fibroblasts laid down a microexudate carpet on the surface of Petri dishes and that this carpet exerted a growth-enhancing activity on sparsely seeded fibroblasts[3,4]. Although the microexudate was thought to be composed mainly of glycoproteins, its exact chemical nature has not been known[3-5]. Here we report the solubilisation and purification of a growth-enhancing protein from the microexudate of cultured chick embryo fibroblasts.

Kondo and Sakai[6] extracted a cell aggregation factor by dissociating sea urchin embryos with 1 M urea–5 mM EDTA solution and showed that this factor was precipitated in the presence of calcium ions. This method was used here for the extraction and purification of the exudate of cultured fibro-

Fig. 1 Purification of the growth-enhancing protein on a column of Sephadex G–200. Calcium precipitate obtained from 100 Petri dishes (10 mg protein) was dissolved in 1 ml of 6 M urea–10 mM EDTA at pH 8.0, stored at 4 °C for 2 weeks and then loaded on a column of Sephadex G–200 (1.5 × 75 cm). Elution was carried out with 10 mM Tris–HCl buffer containing 0.1 mM EDTA at pH 7.5 and fractions of 4 ml were collected. Aliquots of 0.2 ml were used to determine the growth-enhancing activity on sparse cell cultures in the same way as described in Table 1. The arrows indicate the positions of bovine serum albumin and ovalbumin used as the standards.

blasts. Monolayer cultures of chick embryo cells were prepared from 9 or 10-d-old chick embryos in Eagle's MEM supplemented with 5% foetal bovine serum. Cells were cultivated for 3–4 d until they reached confluence in 10-cm Petri dishes. Media was discarded, cell layers were washed twice with phosphate buffered saline containing 0.1 mM EDTA and incubated with 5 ml of 10 mM Tris buffer containing 1 M urea and 5 mM EDTA (pH 8.3) at 37 °C for 30 min or at room temperature for 2 h. The cells became round and tended to become detached from dishes, and they were then dissociated from the dishes by gentle pipetting. More than 99% of cells were viable as judged by staining with trypan blue. After removal of cells and debris, the extract from 100 dishes was concentrated to 50 ml with a Diaflo PM–10 membrane. The crude extract showed strong growth-enhancing activity when added to sparsely seeded cell cultures (Table 1, experiment *a*). The maximum growth-enhancement was obtained by 40 μg ml^{-1} of the crude extract, but the extract at higher concentrations was somewhat inhibitory to the cell proliferation. This effect was caused by a macromolecular growth inhibitor separated by subsequent purification (unpublished work). Quantitative assay of the growth-enhancing activity was difficult because the assay depended strictly on the inoculum density and physiological condition of the cells and because of the existence of inhibitory substances. The degree of subsequent purification, however, could be estimated roughly in terms of the doses required for maximum enhancement.

Table 1 Growth-enhancing activity of the crude extract and calcium precipitate on cultured chick embryo fibroblasts

Experiments	Dose (protein content μg ml^{-1})	Stimulation of growth (Cell no. × 10^{-3} cm^{-2})
a, Control		2.0 (±0.3)
Crude extract	2	7.9 (±2.3)
	10	15.8 (±3.1)
	40	22.3 (±2.4)
	80	9.3 (±2.0)
b, Control		0.7 (±0.2)
Calcium precipitate	2	2.6 (±0.2)
	5	2.9 (±0.4)
	10	4.6 (±0.2)
	20	3.7 (±0.3)
Calcium–supernatant	5	0.8 (±0.1)
	10	0.8 (±0.1)
	20	0.5 (±0.2)

All samples were dialysed against 10 mM Tris–HCl buffer containing 0.1 mM EDTA at pH 7.5 before the determination of the growth-enhancing activity. Aliquots of 0.02 to 0.2 ml of samples were sterilised in 3.5 cm Falcon plastic Petri dishes by brief ultraviolet irradiation (at a distance of 30 cm from a 15 W germicidal lamp for 5 min). Cultivation was started at a density of 500–1,000 cells cm^{-2} in 2 ml of Eagle's MEM containing 5% foetal bovine serum, and the numbers of cells were counted after 7 d. At these low cell densities, the growth rate in the control plates was very low[3]. All experiments were done in duplicate. Protein content was determined by the method of Lowry *et al.*[10].

The concentrated extract was dialysed against 10 mM Tris–HCl buffer containing 10 mM calcium chloride at pH 7.5. The white precipitate which appeared in a dialysing tube (about 25% of total protein) was collected by centrifugation and dissolved in 6 M urea–10 mM EDTA at pH 8.0. The activity was found only in the calcium-precipitate fraction (Table 1, experiment *b*). Since this fraction showed maximum enhancement at 10 μg ml^{-1}, it was concluded that almost all the activity was recovered in the calcium precipitate.

The calcium precipitation was repeated again and the precipitate (about 20% of total protein in the crude extract) was dissolved in 1 ml of 6 M urea–10 EDTA at pH 8.0. After storage at 4 °C for two weeks, the materials were fractionated on a column of Sephadex G–200. The growth-enhancing activity was eluted as a single peak, between the positions of bovine serum albumin and ovalbumin (Fig. 2). This peak contained a single protein as shown by polyacrylamide gel electrophoresis

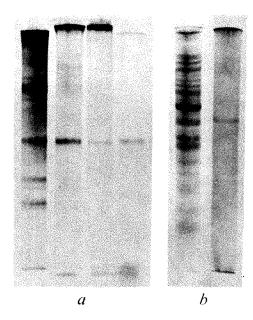
a   *b*


Fig. 2 Patterns of polyacrylamide gel electrophoresis with or without SDS at each purification step. *a*, Electrophoresis in 7.5% gels without SDS at pH 8.1 (ref. 11). From left to right; crude extract, first calcium precipitate, second calcium precipitate, and purified protein. *b*, SDS–polyacrylamide gel electrophoresis in 10% gels[12]. Left, crude extract; right, purified protein. The molecular weight of the purified protein was estimated to be 48,000 (mean of several experiments) using bovine serum albumin, ovalbumin and lysozyme as the standards.

with or without SDS (Fig. 3), of molecular weight about 48,000. This value agreed with the results of Sephadex G–200 column chromatography (Fig. 2). About 400 μg of purified protein (1.5% of total protein in the crude extract) was obtained from 100 dishes. Prolonged treatment of the calcium precipitate in urea–EDTA solution was necessary to dissociate the active materials into monomers of molecular weight 48,000. When this treatment was reduced, two additional peaks of activity were usually found after fractionation on Sephadex G–200, one corresponding to a molecular weight of about 100,000 and the other at the void volume position. In these procedures, it should be also noted that the abrupt addition of calcium chloride often caused a drop in the pH, resulting in the coprecipitation of inactive materials.

Figure 4 shows the effect of purified protein on the growth rate of cultured fibroblasts seeded at low cell density. The purified protein exerted its maximum growth-enhancing effect at 1 to 2 μg ml^{-1}, and the activity was lost completely by treatment with 0.1% trypsin at 37 °C for 30 min. Primary cultures of mouse embryo cells was also stimulated. The activity was retained after brief ultraviolet sterilisation, after treatment with urea or several kinds of detergents, and after freezing–thawing or storage of the solution at 4 °C for at least 2 months. The protein tends to precipitate at a pH lower than 5.0 or in the presence of a small amount of calcium or magnesium ions. Although preliminary experiments indicated that radioactive glucosamine was incorporated into this protein, chemical compositions have not yet been determined because of low yields.

The present investigation has proved that urea–EDTA solution[6] is also useful for the extraction of cell surface or extracellular materials of higher animals with minimum destruction of cells, because 1 M urea solution is nearly isotonic with the cells. We have isolated the same growth-enhancing protein from chicken embryonic tissues by the direct extraction with 1 M urea–5 mM EDTA solution (Y.Y., unpublished).

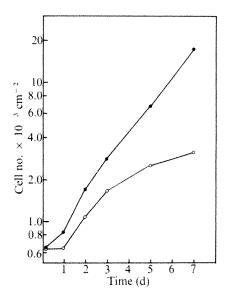
As expected previously[1–4], the purified protein has properties characteristic of pericellular structural proteins, indicating that this protein is responsible for the growth-enhancing activity of


Fig. 3 Effect of purified protein on the growth rate of cultured fibroblasts at low cell density. ○, Control; ●, 1 µg ml^{-1} of the purified protein was added at the start of the cultivation.

conditioned media or feeder layers. Calcium ions may be required for the maintenance of the structural integrity and growth-enhancing activity of the microexudate carpet. In this respect, the carpet protein should be distinguished from humoral growth regulators such as hormones, serum components or fibroblast growth factor[7]. Apparently it resembles closely the "mesenchymal factor" which was partially purified from chick embryonic tissues by Ronzio and Rutter[8] with respect to its structural protein nature, the molecular weight of the monomer, trypsin-sensitivity, possible contribution of calcium ions for activity, and in its localisation at cell surfaces[9]. These factors may offer a molecular and morphological basis for understanding the contact or short range interactions affecting the proliferation of animal cells, with special reference to the functions of cell surfaces.

We thank Dr L. Hayflick for a critical reading of the manuscript.

Permeability of cell junction depends on local cytoplasmic calcium activity

MANY kinds of cells are coupled by junctions consisting of membrane channels through which molecules of a certain size range can flow freely from one cell interior to another[1]. It has been proposed that the permeability of the junctional channels depends on the concentration of free ionised calcium in cytoplasm ($[Ca^{2+}]_i$) (ref. 2). This hypothesis is supported by two classes of experiments. In one, the interior of a coupled cell system is allowed to exchange freely with a known $[Ca^{2+}]$ in the exterior, through a hole in the (non-

junctional) membrane; junctional conductance is reduced (uncoupling) when the $[Ca^{2+}]_i$ is above $5{-}8 \times 10^{-5}$ M (ref. 3). In the other class, uncoupling ensues when the (closed) cell system is treated with inhibitors of energy metabolism or with Ca^{2+} ionophores[5], or on exposure for long periods to Ca,Mg-free medium or to Li medium[6]; in these conditions a rise in $[Ca^{2+}]_i$ may be expected because of known properties of cellular Ca metabolism[7,8]. Here, we demonstrate the changes in $[Ca^{2+}]_i$ together with those in coupling in three of these conditions, using aequorin to display the distribution of Ca^{2+} in the cell. It will be shown that the uncoupling is, indeed, in each case associated with a rise in $[Ca^{2+}]$. Furthermore, by local injection of Ca^{2+} into the cells, it will be shown that uncoupling ensues when the rise in $[Ca^{2+}]_i$ occurs at the junction, but not when it occurs at other regions in the cell.

Chironomus salivary glands were isolated in physiological medium as described previously[4], except that the medium contained 12 mM Ca and no Mg. Purified aequorin was injected into one or two adjacent cells. This protein reacts with Ca^{2+}, emitting light. The emission, approximately proportional to $[Ca^{2+}]^2$ (ref. 9), provides a convenient $[Ca^{2+}]_i$ indicator[10–12]. The aequorin had no apparent adverse effects; membrane potentials and coupling were maintained for several hours. Light emitted inside the cells was guided by a light pipe to a photomultiplier. In addition, a television camera coupled to an image intensifier viewed the cell luminescence through a microscope (Fig. 1). This novel aspect of aequorin technique enabled us to see where the light was emitted inside the cells with a resolution of 5 µm. Ca buffered with EGTA (to stabilise the $[Ca^{2+}]$) was pressure-injected into the cell containing the current source, while electrical coupling between this cell and a contiguous cell was measured as shown in Fig. 1. Current pulses, membrane potentials, their displacements, and photocurrent

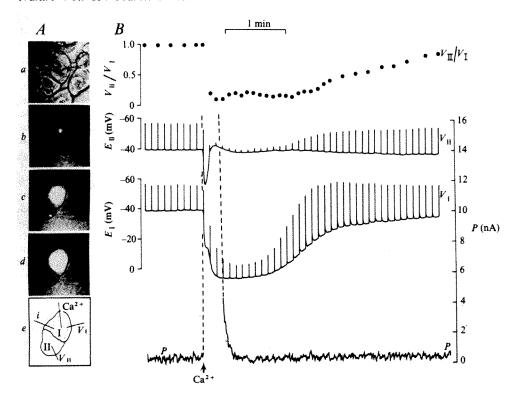
Fig. 1 Television camera coupled to image intensifier by a light guide views the aequorin luminescence of the cells through microscope (darkfield); luminescence is also measured by photomultiplier. Electrical coupling is measured with the aid of three microelectrodes, by pulsing current (i) between the inside of cell (I) and the outside and measuring the resulting steady-state changes (V) and membrane potentials (E) in I and adjacent cell II.


Fig. 2 Ca^{2+} injection. *A*, Darkfield television pictures (*b-d*) of aequorin luminescence in a cell, produced by three puffs of 5×10^{-5} M free Ca (buffered) of increasing magnitude, delivered to cell centre. The pictures are videotape photographs each taken at the time of maximum luminescence spread. Cell outlines are traced by superposition of brightfield video picture (*a*); cell diameter ~ 100 μm. Puffs *b* and *c* do not reach the junctions of the cell and do not affect coupling. Puff *d* reaches one junction and causes transient uncoupling, as shown in *B*: chart records of photomultiplier current P, E_I, E_{II}, V_I, V_{II} ($i = 4 \times 10^{-8}$ A); and plot of coupling ratio V_{II}/V_I. *e*, Cell diagram showing locations of microelectrodes and of Ca injection micropipette; dotted cell preinjected with aequorin.

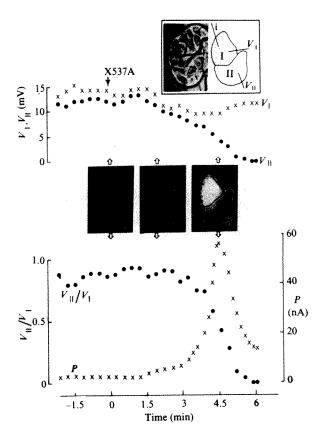
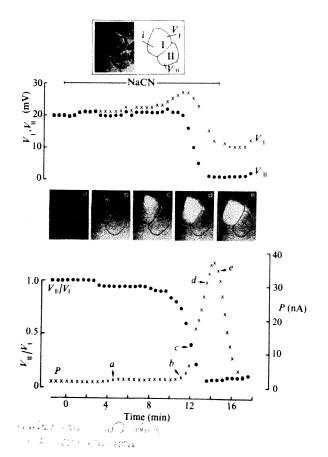
were displayed on a chart recorder and on a storage oscilloscope on to which a second television camera was focused. The two camera outputs were displayed together on a monitor and videotaped. Thus, we had continuous and simultaneous information on the electrical parameters and on the relative local Ca^{2+} activities inside the cells.


Short single injection pulses of $5-10 \times 10^{-3}$ M free Ca^{2+} into healthy cells produced aequorin glows that were confined to the immediate vicinity of the tip of the injection pipette (Fig. 2). Evidently the Ca^{2+} is prevented from diffusing freely through the cytoplasm and seems to be sequestered by intracellular elements[7,13,14]. When such an injection was made into the cell centre (cell radius, 50 μm), junctional coupling was unaffected. When it was close to a cell junction, the coupling fell (uncoupling), and this effect was confined to the junction at which the local rise in $[Ca^{2+}]$ had occurred. Longer or more frequent injections of this sort, or prolonged Ca^{2+} iontophoresis between electrodes placed in two adjacent cells, produced glows that were diffuse over the entire cell. Then all junctions of the injected cell uncoupled. Presumably the intracellular sequestering capacity was saturated under these conditions. (When mitochondrial sequestering of Ca was blocked by ruthenium red[15], the glow was diffuse even with the shorter injection pulses.) Control injections of 0.15 M KCl did not affect coupling of $[Ca^{2+}]_i$. Massive KCl injections, however, produced transient and diffuse rise of $[Ca^{2+}]_i$ associated with transient uncoupling.

Treatment with ionophore A23187 (Lilly, 2×10^{-6} M) or X537A (Hoffman LaRoche, 1×10^{-5} M) led to enhanced Ca influx which was detectable within 1 min as a diffuse glow that increased progressively during the next 10 min. The rise in $[Ca^{2+}]_i$ was invariably associated with uncoupling, the coupling ratio diminishing progressively with rising $[Ca^{2+}]_i$ (Fig. 3).

Similar results and equally good correlation between rising $[Ca^{2+}]_i$ and uncoupling were obtained when the cells were poisoned with sodium cyanide (5×10^{-3} M) in medium containing Ca as well as in Ca-free medium (Fig. 4).

Prolonged exposure to Ca,Mg-free medium led to a rise in $[Ca^{+2}]_i$. This rise, evidently nurtured by intracellular Ca stores (as Na accumulates inside the cells in Ca-free medium[16], the mitochondria may release Ca^{17}), was asso-

Fig. 3 Ionophore X537A. Exposure to 1×10^{-5} M X537A starts at black arrow and continues throughout the remainder of experiment. Top to bottom: V_I V_{II} ($i = 4 \times 10^{-8}$ A); darkfield television pictures of luminescence (open arrows indicate their time correspondence); coupling ratio V_{II}/V_I; photocurrent P. Cell I depolarises as P rises above background, reaching zero membrane potential at time 9 min. Peak of luminescence in cell II (not shown) occurred 5 min after peak in I. *Top inset:* bright field television picture and cell diagram; cells I and II contain aequorin.


ciated with uncoupling. These experiments were particularly instructive, because $[Ca^{2+}]_i$ and coupling fluctuated: rise and fall in $[Ca^{2+}]_i$ were associated, respectively, with fall and rise in coupling.

In cells with good membrane potentials ($\geqslant 40$ mV), the uncouplings produced by single short Ca pulses generally were spontaneously reversible (Fig. 2). Presumably the cells rid themselves of the excess Ca by sequestering it into mitochondria and by pumping it out. With more massive injections, or after ionophore treatment or prolonged exposure to Ca,Mg-free medium, the uncouplings did not reverse spontaneously. It was then possible to reverse the uncouplings by injection of Ca–EGTA solution yielding $\leqslant 10^{-6}$ M free Ca.

In all these conditions, the rise in $[Ca^{2+}]_i$ was accompanied by depolarisation and fall in input resistance. This effect, a consequence of increased non-junctional membrane permeability to Na^+ (refs 18 and 19), was particularly pronounced when the aequorin glow was diffuse; the depolarisation then paralleled closely the onset of uncoupling. Thus, the question presented itself of whether $[Ca^{2+}]_i$ or depolarisation is the primary cause of uncoupling. To resolve this question, we injected Ca^{2+} while clamping the membrane potential at resting level with a feedback system. Uncoupling ensued none the less whenever the glow reached a junction. Depolarisation is thus clearly not necessary for uncoupling.

In a complementing series of experiments, the cells were exposed to high K (90 mM) medium. Within 2–5 min of application of K medium, the membrane potentials fell to near zero or overshot zero by 5–10 mV. The depolarised cells nevertheless stayed well coupled much longer, in some cases for several hours. Eventually, and rather abruptly, the cells uncoupled; and this was associated with an abrupt rise

Fig. 4   Cyanide. Cells in Ca-free medium. Exposure to 5×10^{-3} M sodium cyanide (top signal). Time correspondence of television pictures *a–e* is marked on the *P* curve. $i = 4 \times 10^{-8}$ A. Cell I depolarises as *P* rises, reaching zero membrane potential at time 17 min.

in $[Ca^{2+}]_i$. Depolarisation is thus also not sufficient for uncoupling.

In conclusion, the cytoplasmic free Ca concentration in the domain of the junction seems to determine the permeability of the junction. We do not know the mechanism by which the calcium ion alters the permeability. Conceivably Ca^{2+} binds to the junctional membrane changing the conformation of the junctional cell-to-cell diffusion channels[2]. We favour this simple notion, because as our results show, the permeability change is readily reversed when the normal $[Ca^{2+}]_i$ is restored in cells with normal Ca-pumping and Ca-buffering ability.

We thank Dr O. Shimomura for aequorin and Drs R Llinás and C. Nicholson for the use of a voltage-clamp system. The work was supported by research grants from the US Public Health Service and the National Science Foundation.

Modification of a model membrane structure by embedded photochrome

PHOTOREGULATED processes are of interest in diverse biochemical phenomena such as photosynthesis, vision, phototropism and phototaxis. The capture of a photon of appropriate energy, as the first event, triggers, or is followed by, subsequent steps such as electrical potentials or enzyme activity. In this respect, Erlanger and co-workers[1] have shown that some processes such as the catalytic activity of certain enzymes, which are intrinsically insensitive to light, may be modulated or regulated by the presence of appropriate photochromic molecules.

The primary process of photon capture in vision, photosynthesis and perhaps other related phenomena, is the absorption of light energy by 'sensor' molecules Frequently, such 'sensor' molecules form part of, and are embedded in, membranes. The delineation of the step starting from photon absorption by the membrane embedded molecule and ultimately leading to the final response is of considerable importance. Such photoinduced processes may occur by means of a direct link between the 'sensor' molecule and the proteins (or other molecules) connected with the response, with the membrane providing an essentially inert milieu; or they may involve mediation by the membrane in which the 'sensor' molecule is incorporated.

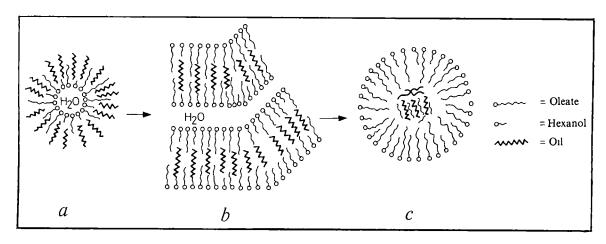
An investigation into the plausibility of the latter proposition would involve monitoring the changes that might occur in the membrane structure on photon absorption by the 'sensor' molecule; in addition, an assay of the activity


Fig 1 Molecular organisation of the water–oil microemulsions *a c,* clear dispersions of water in oil (0–0 6), and oil in water (water–oil ≥ 1 2), respectively *b*, Birefringent lamellar multi-bilayer system (water–oil = 0 6–1 2)

of a membrane-bound protein (or enzyme) would be desirable Photo-induced changes in the conformation of a model membrane have been observed by Verma *et al*[2], who studied the electron spin resonance of a spin-labelled phospholipid multibilayer film in the presence of incorporated retinal We report here preliminary results on photoinduced conformational changes in a model membrane, and concomitant changes that occur in the esteratic activity of α chymotrypsin, incorporated in the model membrane

Our model membrane system is the microemulsion obtained by the dispersion of water and hexadecane using the amphipathic potassium oleate as the emulsifier and hexanol as the cosurfactant The properties of such systems have been shown by Shah[3] to be relevant to membranes Water–hexadecane (0 7 1 0 to 1 3 1 0 (v/v)) results in a birefringent phase in which the molecular organisation is as shown in Fig 1*b* Compositions with lower ratios yield clear dispersions of water in oil (Fig 1*a*), whereas higher ratios (1 2 1 0 to 1 4 1 0) result in clear dispersions of oil in water (Fig 1*c*) The relevant region is the intermediate water–oil composition depicted in Fig 1*b*, providing a model for membranes as has been verified by several physical measurements[4] We chose this region because it is structurally similar to liposomes, easily monitored by electrical resistance measurements, and, being in the liquid phase, quantitative spectral measurements and enzyme assays can be conveniently done The response of this oil–water lamellar system to drugs and to electrolytes is similar to those of liposomes and of other membrane models[3]

The photosensor molecules chosen were azobenzene and azobenzene-*p*-carboxylic acid methyl ester Both these compounds are known[5] to undergo reversible isomerisation from *trans* to *cis* conformations and back again on illumination with photons of appropriate wavelengths The photoisomerisation produces long lived isomer species which relax with time into the equilibrium isomer population of the predominantly *trans* form In a typical experiment, a small amount of the photochrome was added to the model membrane (photochrome–hexadecane molar ratio 1 300) and the electrical resistance of the membrane followed using the method of Shah[4] Measurements were made on the system over a wide range of water–oil compositions, and in the presence of the photochrome in its equilibrium isomer population, in its *cis* form and the *trans* form, each of which is produced by flooding the membrane containing the photochrome with light of appropriate wavelength for several minutes The variation in the resistance of the microemulsion as a function of the water–oil ratio is shown in Fig 2 We were particularly interested in the region where the system adopts a liquid crystalline lamellar molecular arrangement The

arrow A in Fig 2 shows the resistance changes that occur in the model membrane when the photochrome is in its equilibrium isomer population (on the curve), on converting it completely to the *trans* isomer (illumination with a 250 W mercury lamp using a Corning CS 373 filter 400–500 nm window for 8 min, resistance at lower end of arrow A), and photoisomerising it completely into the *cis* form (using same lamp with a Corning CS 760 filter, 300–400 nm window for 8 min, resistance corresponds here to the top of arrow A) On standing, the photochrome reverts to its equilibrium isomer ratio and the resistance of the system also returns to the original value on the curve Such changes in the resistance are reversible over several cycles of photoisomerisation, and occur both with azobenzene or the azobenzene ester as the photochrome The photochrome molecule, itself non-conducting, does not contribute to the resistance, that is, the variation in resistance with composition shown in Fig 2 is essentially the same with or without the photochrome, in the absence of light Also, there is no change in the resistance of the system on illumination in the absence of the photochrome, thus discounting the possibility of photoinduced perturbation of the microemulsion structure by itself Changes in the resistance of the type shown in arrows A and B of Fig 2 also occur, but less significantly, in the clear regions of the microemulsion

The changes in the resistance may result from a perturbation in the molecular organisation within the lamellar model membrane induced by the conformational change occurring in the incorporated photochrome on photoisomerisation This interpretation is supported by the reversible changes from the birefringent phase to the clear phase and back, observed on the *trans* to *cis* to *trans* interconversion of the photochrome, in the microemulsion of water–oil composition (0 7 1 0) corresponding to the borderline situation between clear dispersion and the lamellar phase Shah[4] has observed anomalous changes in the resistance of such lamellar water–hexadecane system on the introduction of anaesthetic drugs, and has interpreted them as resulting from perturbations in the molecular organisation within the lamellae Our results and interpretation agree with those of Verma *et al*[2] who monitored the electron spin resonance signals of a spin label incorporated in a similar bilayer model system It therefore seems possible to induce perturbations in the structure of a model membrane by altering the geometric shape or conformation of an imbedded photochrome molecule

To investigate whether such membrane structural perturbations could result in a change in the activity of an enzyme incorporated in the membrane, we monitored the ester hydrolytic activity of α chymotrypsin dissolved in the

membrane containing azobenzene and the azobenzene ester separately We chose the lamellar region of the emulsion, and the simplified Bender–Kezdy method of assay[6] with p-nitrophenyl acetate as the substrate The activity of the enzyme was monitored by incubating the solution of the enzyme in the membrane with the substrate in the presence of azobenzene for 10–15 min and spectrophotometrically following the liberated p-nitrophenol absorbance with time (see Fig 2) The photochrome–azobenzene carboxylic ester was unsuitable since it was found to directly bind to chymotrypsin Azobenzene showed no appreciable binding or modification of the catalytic activity of chymotrypsin in an aqueous buffer solution control If the activity of chymotrypsin towards p-nitrophenyl acetate in the model membrane in the presence of the equilibrium population of azobenzene is taken as unity, the activity when the azobenzene was exclusively in the *cis* form (photoisomerised at 300–400 nm for 10 min) was found to be fourfold greater, whereas the activity of the enzyme in the presence of exclusively *trans* photochrome (irradiation at 400–500 nm for 8 min) was about 0 6 Since azobenzene does not seem to bind directly to the protein in our system or modify its catalytic activity in the control, and since chymotrypsin itself is insensitive to light[1], these results have been interpreted as follows Photoisomerisation of the 'sensor' photochrome causes a rearrangement of the membrane structure, and this structural change results in a slight conformational perturbation in, and therefore the activity of, the membrane-bound protein

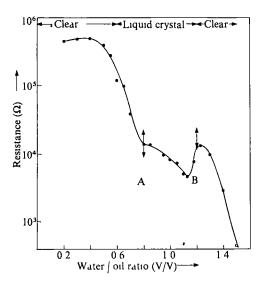
These model studies may be of relevance to the photophysical changes that occur in the rhodopsin molecule, on bleaching, in the retinal rod outer segment disk membranes On bleaching, the rhodopsin molecule 'sinks' into the membrane[7] It is possible that photoisomerisation of the retinal molecule alters the molecular organisation of the


Fig 2 Variation of the electrical resistance of the water–oil dispersions with composition Photochrome (1 5 mg) is added to a mixture containing 1 ml hexadecane, 0 2 g potassium oleate and 0 4 ml hexanol The amount of water is varied to obtain appropriate compositions The resistance was measured using a Philips PR 9500 conductivity bridge at 1 KHz, with platinum electrodes 0 8 cm apart Temperature 28 ± 1 °C For the assay, 0 6 mg of p-nitrophenyl acetate in 0 2 ml hexanol was added to a mixture of 0 38 ml hexanol, 1 0 ml hexadecane, 1 0 ml H₂O, 3 2 mg azobenzene, 0 2 g potassium oleate and 3 mg chymotrypsin (σ) that has been irradiated for 10 min at the chosen λ The A_{400} of the released p-nitrophenol was measured at 90 s intervals and the rate of release was calculated from the linear (later) portion of the release curve The reference cuvette contained the same solution (minus substrate) and was taken through all the steps as the sample Path cells (1 cm) were used in a Beckmann DU instrument (28 ± 1 °C)

Effect of temperature on immune damage of liposomes prepared in the presence and absence of cholesterol

SINCE the report by Kinsky[1] that liposomes containing lipid haptens could be damaged by activated complement, it has become generally accepted that the lytic attack mechanism of the complement system acts on the lipid matrix of the cell membrane In spite of the accumulation of experimental observations[2] concerned with liposomal damage by activated complement, there is little detailed information about the mechanism by which the damage occurs Inoue and Kinsky[3] suggested that complement did not damage liposomes as a result of degradation by 'phospholipase' (see also ref 4) It was therefore postulated that the lytic action of complement may resemble that of 'detergent'[2–4] Hydrophobic regions in the terminal complement components may penetrate into lipid bilayers, diminishing the non-polar intermolecular attractive forces between lipids Muller-Eberhard et al [5] proposed a model for the molecular assembly of the C5–9 complex on the surface of cells under attack by complement They suggested that complete assembly of the C5–9 complex augmented the detergent effect of C5

We reported previously that liposomal damage induced by lysolecithin[6], polymyxin B (ref 7) and Prymnesin[8] required certain states of fluidity in lipid bilayers, but it is not known whether complement-induced liposomal damage is also influenced by fluidity of bilayers We report here that, using dipalmitoyllecithin liposomes, the complement action requires some fluid conditions of membranes

Immune-sensitive liposomes were prepared using the methods of Kinsky et al [9] and dipalmitoyllecithin liposomes without cholesterol were prepared as described previously[10] Forssman antigen isolated from horse spleen was donated by Dr A Makita, Hokkaido University Antisera against Forssman antigen were prepared by intravenously injecting sheep erythrocyte membranes into rabbits The release of glucose marker was enzymatically assayed as described previously

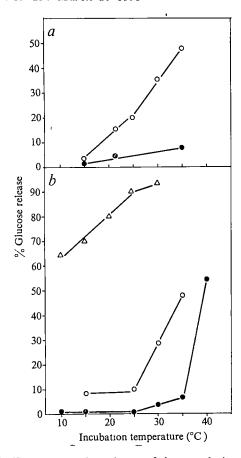
Dipalmitoyllecithin liposomes (no cholesterol) sensitised with Forssman antigen were incubated with excess amounts of antiserum and guinea pig serum (complement) at various temperatures Damage of the liposomes by antibody and complement was markedly dependent on temperature (Fig 1a) Below 15 °C, the reaction was not detectable, but glucose release was observed at higher temperatures Up to 35 °C, the reaction increased with temperature Since spontaneous release of glucose occurred from the liposomes above 37 °C (ref 10), which resulted from the so-called phase separation of lipid bilayers, the exact temperature dependence of complement-induced permeability change could not be examined above this temperature The


Fig 1 Temperature dependence of liposomal damage by activated complement, methylated bovine serum albumin and Triton X-100 Liposomes were prepared from mixtures of dipalmitoyllecithin and dicetyl phosphate (1 0 1) with or without 10 μg Forssman antigen per μmol phospholipid a, Liposomes without antigen (●) and with antigen (○) were incubated with 11 μl anti-Forssman antiserum and 34 μl guinea-pig serum at various temperatures for 30 min b, Liposomes without antigen were incubated alone (●), with 35 μg Triton X-100 (△) or 12 μg methylated bovine serum albumin (○) for 10 min at various temperatures

by the same procedure The results indicated that sensitivities of liposomes both with and without cholesterol against complement were not significantly different (Fig 3) We therefore concluded that cholesterol does not have any influence on the sensitivity of liposome to antiserum and complement

There was no difference in sensitivity towards antiserum and complement between liposomes of dipalmitoyllecithin, dimyristoyllecithin and egg lecithin, whereas rather different sensitivity was reported between egg lecithin and beef sphingomyelin liposomes[11] Complement-dependent glucose release from dipalmitoyllecithin liposomes, egg lecithin liposomes and dimyristoyllecithin liposomes, all of which contained 50 mol% of cholesterol, was not as influenced by incubation temperature as the release from dipalmitoyllecithin liposomes without cholesterol (Table 1)

Incorporation of cholesterol into dipalmitoyllecithin liposomes has been shown to have complicated effects on the permeability of glucose, it may give a dual effect, that is, the condensing and fluidising effect on bilayers of dipalmitoyllecithin Dipalmitoyllecithin liposomes without cholesterol showed very little reactivity with antiserum and complement at 21–23 °C, whereas those with cholesterol were damaged in the same reaction conditions (Table 1) The effects of cholesterol incorporation on immune damage of liposomes may be caused by the fluidising effect Introduction of cholesterol generally suppressed the sensitivities of liposomes towards various lytic reagents such as lyso-

liposomes without Forssman antigen released little glucose throughout the temperature range 10–35 °C

The effect of antiserum concentration on the loss of marker from dipalmitoyllecithin liposomes which were prepared with a certain amount of Forssman antigen (10 μg per μmol phospholipid) is shown in Fig 2 The experiments were performed at 35 °C From these curves, we determined the amount of antiserum required for glucose release under conditions in which antigen content and concentration of complement source are not rate limiting Liposomes prepared with dipalmitoyllecithin and dicetyl phosphate showed almost the same sensitivity towards antiserum as those made with a mixture of dipalmitoyllecithin, dicetyl phosphate and cholesterol (Fig 2) The amount of fresh guinea pig serum (complement) necessary for marker release was determined

Fig 2 Effects of antiserum concentration on dipalmitoyllecithin liposomes prepared with Forssman antigen Liposomes containing 10 μg per μmol phospholipid were prepared with and without cholesterol as described in the legend to Table 1 Compositions of liposomes were as follows diaplmitoyllecithin (DPL), dicetyl phosphate (DCP) and cholesterol (Chol) in the molar ratio of 1 0 1 1 (●), dipalmitoyllecithin (DPL) and dicetyl phosphate (DCP), (○) 1 0 1 1

Table 1 The specific damage of liposomes containing antigen by antibody and complement

Lecithin	C14 0		C16 0				Egg

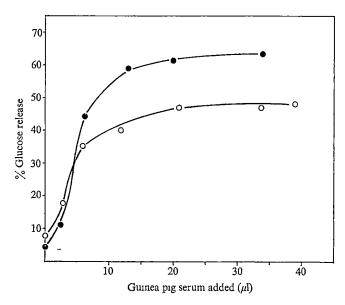
Liposomes were prepared from various lecithins and 10 μg Forssman antigen per μmol phospholipid without or with cholesterol Glucose release was determined after 30 min incubation at 21–23 or 35 °C with various sera as indicated The amounts of each serum added were as follows guinea pig serum (GPS), 35 μl, heated guinea pig serum (heated GPS), 35 μl, rabbit anti-Forssman serum (rabbit AS), 30 μl


Fig 3 Effects of guinea pig serum concentration on dipalmitoyl-lecithin liposomes prepared with Forssman antigen Liposomes containing 10 μg per μmol phospholipid were prepared with (●) and without (○) cholesterol The liposomal compositions were as described in Fig 2 Glucose release was determined after liposomes were incubated with varying amounts of guinea pig serum in the presence of 11 μl antiserum at 35 °C for 30 min

lecithin[6], polymyxin B (ref 7) and some basic proteins[12] The condensing effect of cholesterol may interfere with the penetration of these molecules into bilayers, but the suppressive effect of cholesterol could not be observed in the case of complement-induced damage of liposomes Dipalmitoyllecithin liposomes with 50 mol% of cholesterol are among the most resistant liposomes yet reported, that is, they resist the action of Triton X-100 (ref 10), lysolecithin[6], polymyxin B (ref 7) and methylated bovine serum albumin (T K and K I , unpublished) Activated 'hydrophobic' complement components may penetrate into such 'highly condensed' membranes

Methylated serum albumin is one of the basic proteins with ability to damage liposomes The mechanism by which the protein damages lipid bilayers may be considered as follows[13] interaction of positively-charged residues of proteins with negatively-charged components of the membranes, change in conformation of the proteins, penetration of exposed 'hydrophobic' regions of proteins into the bilayers The reaction of dipalmitoyllecithin liposomes with methylated bovine albumin also depends markedly on the incubation temperature (Fig 1b) Temperature dependence of methylated albumin-induced liposomal damage was rather similar to that of immune damage of the liposomes On the other hand, the detergent Triton X-100 could affect the liposomes to almost the same degree over the temperature range 10–35 °C Molecules of Triton X-100 can easily penetrate into dipalmitoyllecithin bilayers, whereas protein molecules can not penetrate into bilayers of membranes whose arrangement is too condensed With increased temperature, arrangement of hydrophobic regions of the membrane becomes loose and allows proteins to penetrate It is quite conceivable to assume that the mechanism of membrane damage by activated complement is rather similar to the mechanism of methylated albumin-induced membrane damage The lower transition or pretransition (about 35 °C) was reported[14] on dipalmitoyllecithin The pretransition has been associated[14] with an increase in mobility of the polar head portion of the lipid The increase in mobility of the polar head portion may allow proteins to penetrate into bilayers

The effect of proteins in altering the phase transition characteristics must also be considered Some proteins could

act as modifiers of the lipid phase transitions Addition of cytochrome C has been reported to lower the transition temperature of lipids[15] Our experimental systems, antibody and activated complement components, may also modify the lipid phase transitions It is possible that the effect of activated complement in lowering the transition temperature of dipalmitoyllecithin may be responsible for our results If true, it should be noted that the binding of antibody molecules could not modify the lipid phase transition

Our results suggest that liposome damage induced by complement requires some fluid condition of membrane Cholesterol does not play an important role in the binding of antibody to antigen on the membrane not in the membrane damage by complement components Simple model systems of immune lysis could be established to investigate the mechanism

We thank Dr S Nojima for discussions and encouragement, and Dr S C Kinsky for comments during preparation of the manuscript

Appearance of β globin synthesis in erythroid cells of Ferrara β[0]-thalassaemic patients following blood transfusion

Homozygous β-thalassaemic subjects from the Ferrara region characteristically do not synthesise β globin[1,2] Some of us have presented previously data which suggest that the addition of ribosome-free supernatant isolated from red blood cells of normal adult individuals or from subjects with homozygous haemoglobin S to Ferrara thalassaemic ribosomal material induces β[A] globin synthesis[3], these results suggested that this *de novo* synthesis was not associated with free normal β[A] globin mRNA From these findings it has been concluded that the mutation of the Ferrara β thalassaemia does not reside in the gene for β globin, which is in fact transcribed into normal β globin mRNA, but in a gene coding for a previously unrecognised factor, indispensable for β globin translation Here we report data which suggest that the reticulocytes from these patients synthesise β globin following normal blood transfusion

Table 1 shows the amount of radioactivity incorporated into α, β and γ globin in the reticulocytes of a homozygous β thalassaemic subject from Ferrara, before and 5, 17, and 24 d after receiving the first blood transfusion α and γ globin synthesis varied only slightly, while the incorporation of radioactive leucine into β globin, undetectable before the treatment, became clearly demonstrable after blood transfusion

As a result of the post-transfusional appearance of β globin synthesis, the ratio of α- to non-α-globin synthesis decreased from 2 6 to more normal values The specific activity of purified

Table 1 ^{3}H-leucine incorporation into α, β and γ globin (separated as in refs 7 and 8) by 0 5 ml of packed red blood cells of a homozygous β-thalassaemic subject from Ferrara, before and after blood transfusion

| | Total radioactivity (c p m) | | | Total globin synthesis (c p m) | % of β globin synthesis | $\dfrac{*^3\text{H-}\alpha\text{-}}{^3\text{H-non-}\alpha\text{-globin}}$ |
Before transfusion	α globin	β globin	γ globin			
30 d before	14,763	0	5,529	20,292	0	2 6
1 d before	15,711	0	6,015	21,762	0	2 6
After transfusion						
5 d after	13,905	4,095	5,520	23,520	42 5	1 4
17 d after	13,440	7,091	5,940	26,571	54 7	1 0
24 d after	15,051	5,514	5,793	26,358	48 7	1 3

0 5 ml of washed red blood cells from a homozygous β-thalassaemic subject from Ferrara, obtained before and after the first blood transfusion at the days indicated, were incubated with ^{3}H-leucine for 2 h at 37 °C, as previously reported[1] After incubation the cells were lysed and the stromal material removed by centrifugation Globins prepared from stroma-free haemolysates by acid acetone precipitation[1] were separated into their individual chains by CM cellulose column chromatography[7,8] The chromatographic pattern was continuously monitored with a Gilford recording Spectrophotometer (Model 2400) at 280 nm and fractions of 2 5 ml were collected Radioactivity determinations were on 0 2 ml from each fraction, in Bray's solution[13], with a Packard Tri-Carb Liquid Scintillation Spectrometer (Model 3003), efficiency for tritium 49 %

Total incorporation into α, β and γ globin was calculated on the radioactivity pattern, drawn after background subtraction
 *^{3}H-non-α-globin synthesis = ^{3}H-β-globin + ^{3}H-γ-globin

β globin, obtained from isolated haemoglobin A, was maximal approximately 13 d after transfusion (see Table 2)

The characterisation of the radioactive protein appearing in the β globin region was carried out in a β⁰-thalassaemic subject studied 20 d after he had received the first blood transfusion Following a standard red blood cell incubation with ^{3}H-leucine, haemoglobin A was isolated by chromatography on Amberlite CG-50[4] and converted into globins[5] Globins were purified further by chromatography on Sephadex G-200[6] Finally the β globin chains were isolated[7,8]

The isolated β globin chains were digested with trypsin and the resulting peptides separated by column chromatography[9] The baseline radioactivity was measured by determining the number of counts in four regions of the chromatogram, one before βT₃ (B1), one between ammonia and βT₈ (B2), one before βT₆ (B3) and one after βT₁₅ (B4) The measured radioactivity (c p m) in the fractions was B1 = 39, B2 = 99, B3 = 77 and B4 = 50 The fractions of the leucine-containing peptides βT₁, 2, 3, 5, 9 and 14, and of peptide βT₁₃, were separately pooled, lyophylised and purified further (see legend to Table 3)

After purification of the leucine-containing peptides βT₁, 2, 3, 5, 9, and 14 their specific activities were determined (Table 3) Four non-leucine-containing peptides were also studied, three of them (βT₆, 7 and 15) were analysed directly after the first chromatography, while peptide βT₁₃ was purified further The purification of peptides βT₁, 2, 5, 9 and 14 was successful, with a good yield in terms of absorbance and radioactivity, peptides βT₃ and 13, although pure by amino acid analysis, were recovered in amounts too low to give acceptable information

The analysis of the results (Table 3) was limited to peptides βT₁, 2, 5, 6, 7, 9, 14 and 15, which nevertheless represent a sizeable amount of the β globin molecule and are good samples of the entire chain, being located at the beginning, in the middle and at the end of the molecule As the radioactivity is present in the five leucine-containing peptides in amounts proportional to the amino acid content, and practically absent in the peptides without leucine, considering the amount of peptide recovered (see Table 3), it can be concluded that the radioactive material analysed in the β⁰-thalassaemic subject under investigation after blood transfusion was β globin Furthermore, the calculated specific activity of leucine in the original isolated globin was 518 8 c p m µmol⁻¹ (assuming 1 0 absorbance unit = 1 mg of protein), close to that of the leucine in the isolated peptides

Figure 1 shows the percentage of β globin synthesis, relative to total non-α-synthesis, demonstrated in 65 subjects examined at different times after blood transfusion β Globin synthesis was present in all subjects except two, in these patients β-synthesis was not present after the first blood transfusion, but appeared after the second As shown in Fig 1, the maximum

β globin synthesis occurred approximately between the 15th and the 20th day after blood transfusion Over the same period and in the same subjects the ratio of α-globin synthesis to non-α-globin synthesis decreased from the usual pretransfusion values to unity (see Fig 2) In two patients, globin synthesis by intact erythroid cells was determined following injection of plasma from two normal adult individuals, no β globin synthesis was detected in either case

The kinetics of the appearance of β globin synthesis after blood transfusion derived from Table 1 and Fig 1 indicates that haemoglobin A synthesis occurs in the patient's cells and not in the transfused red cells In fact in the latter case β globin synthesis should be maximal immediately after transfusion and rapidly disappear during the days following

The occurrence of β globin synthesis in thalassaemic reticulocytes has been confirmed in four experiments in which, 20 d after blood transfusion, the erythrocytes of the donor (of O group) were separated from the erythroyctes of the patient (of A group) by means of lectin precipitation[11,12] Practically all β globin synthesising capacity was found in association with the non-agglutinated thalassaemic red blood cells In the same four samples the amount of non-radioactive β globin, relative to

Fig 1 Relative synthesis of β globin as determined by CM cellulose column chromatography in 55 homozygous β⁰-thalassaemic subjects from Ferrara, following blood transfusion No β globin synthesis was detected either before or 2–3 months after transfusion Methods as Table 1

1 0 ml of washed packed red blood cells, obtained at the days indicated, were incubated with ^{3}H-leucine for 2 h, at 37 °C Stroma-free lysates, obtained as reported in Table 1, were submitted to Amberlite CG-50 chromatography[4] and the purified haemoglobin A' submitted to CM cellulose column chromatography[7-8] for chain separation The subject is the same as that referred to in Table 1

total non-α-globin, measured as absorbance at 280 nm after CM cellulose column fractionation, ranged from 12% to 21%

Control experiments showed that the above technique effectively discriminated between red blood cells of different groups The lectin agglutination experiments, as well as showing that β globin is synthesised by thalassaemic erythroid cells, exclude the possibility that the appearance of β globin synthesis may be a result of bone marrow graft and proliferation of immature red blood cells, possibly present in the, peripheral blood of the donor

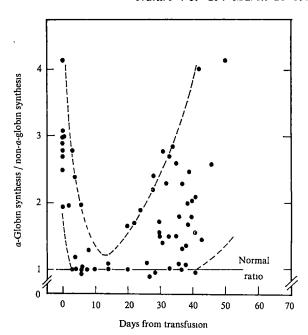
The data reported here strongly suggest the appearance of β globin synthesis in Ferrara thalassaemic erythroid cells after blood transfusion, it is possible that some thalassaemic subjects previously reported in the literature as "β+" may have been transfused β° patients Our findings suggest that the specific inducer of β globin synthesis, previously shown to be present in normal red blood cells[3], can cross the thalassaemic red cell membrane and replace the absent or non-functioning thalassaemic factor in inducing β globin mRNA translation In line with this suggestion is the fact that the maximum of β globin synthesis corresponds approximately with the maximum of red cell destruction Red cell lysis occurs in the reticuloendothelial


Fig 2 Synthesis of α-globin relative to non-α-globin in 55 homozygous β°-thalassaemic subjects from Ferrara, following blood transfusion

system, which is well represented in the spleen, but also in the bone marrow, in the latter therefore the maturing thalassaemic red blood cells could be exposed to a relatively high concentration of normal red cell cytoplasm and, consequently, of the postulated normal β globin 'inducer'

We cannot distinguish at the moment whether the *in vivo* induced β globin synthesis is directed by transfused or by thalassaemic β globin mRNA So far we have been unable to obtain and transfuse to Ferrara thalassaemic patients blood from subjects homozygous for a mutant stable β globin (as in haemoglobin E or haemoglobin C), which would discriminate between these two possibilities Nevertheless the short survival time of the protein synthesising capacity in reticulocytes together with the presence in Ferrara thalassaemic red blood

Table 3 Incorporation of radioactivity into the tryptic peptides of purified β globin isolated from a homozygous β°-thalassaemic subject 20 d after blood transfusion

Leucine-containing peptides	Molecules of leucine per peptide	Recovery of leucine (μmol)	Recovery of radioactivity (c p m)	Specific activity (c p m per μmol leucine)
βT₁	1	1 305	760	582
βT₂	1	1 271	771	606
βT₃	1	0 059	36	607
βT₅	1	0 325	150	461
βT₉	4	2 588	1,615	624
βT₁₄	1	1 220	823	674
Non-leucine-containing peptides		Recovery of peptide (μmol)		
βT₆	0	2 032	151	—
βT₇	0	2 000	39	—
βT₁₃	0	0 075	43	—
βT₁₅	0	2 109	90	—

The fractions containing the leucine-containing peptides βT₁, 2, 3, 5, 9 and 14, and of peptide βT₁₃, were separately pooled, lyophilised and purified further as follows βT₁, 2 and 14 were purified by column chromatography on Aminex 50W-X2, pyridine-acetate linear gradient from pH 3 1, 0 2 M to pH 5 0, 2 0 M, βT₃ and 13 by two successive treatments on Aminex 50W-X2, pyridine-acetate linear gradient from pH 3 1, 0 2 M to pH 5 0, 2 0 M, and a third column chromatography on Aminex AG1-X2, using the elution system described by Schroeder and Robberson[10], βT₅ by column chromatography on Aminex 50W-X2, pyridine-acetate linear gradient from pH 2 75, 0 1 M to pH 4 25, 1 25 M βT₉ by column chromatography on Aminex 50W-X2, pyridine-acetate linear gradient from pH 3 1, 0 2 M to pH 4 25, 1 25 M The profile of the various peptides after rechromatography was continuously monitored at 570 nm The fractions corresponding to the various peptide peaks were pooled and lyophilised Amino acid analysis was done on 1/40th of the lyophyllised material to check the purity of the peptides after rechromatography, and to determine the leucine content necessary for the specific activity determinations The residual material was used for radioactivity measurement The amino acid analyses proved the purity of the various peptides, the radioactivity blank of the rechromatographies ranged between 15 and 40 c p m

cells of untranslated β globin message[3] are good indications that the post-transfusional β globin synthesis is directed by thalassaemic β globin mRNA In both cases, however, the inducer of β globin synthesis has to become available within the thalassaemic erythroid cells (in which this molecule is lacking or not functioning[3]) to permit β globin synthesis

Neurosecretory cells in insect brain and production of hypoglycaemic hormone

INSECTS have a hyperglycaemic hormone, produced by neurosecretory cells of the corpus cardiacum (CC) This hormone stimulates the production of the major blood carbohydrate trehalose from glycogen stored in fat body cells[1] No hypotrehalosaemic hormone has so far been reported and the level of blood trehalose has been thought to depend on the secretory activity of the CC neurosecretory cells controlled by nerves from the brain[2,3], the relationship between production and consumption of trehalose, which in many insects, including flies, serves as fuel for flight Also, in vitro experiments indicate that medium containing trehalose can inhibit the synthesis or liberation of trehalose from fat body cells, and it has been suggested that such feedback control is an important factor in the natural regulation of trehalose formation[4,5] It was therefore surprising to find that seven decapitated 6-d-old blowflies, Calliphora erythrocephala, not only remained alive for 30 h, during which locomotion and heart beat continued, but that their blood trehalose level had increased from 21 9 g l^{-1} (±4 09 s e m) to 113 2 g l^{-1} (±9 07 s e m)

There are several possible explanations for the extreme hyperglycaemia of the decapitated flies (Fig 1) A hyperglycaemic factor could have been released from the CC, or from the corpus allatum (CA), or from the thoracic ganglion Uncontrolled release might then be ascribed to removal of the brain Alternatively, a hypoglycaemic hormone could be produced in the brain or secreted by some unknown endocrine organ controlled by the central nervous system

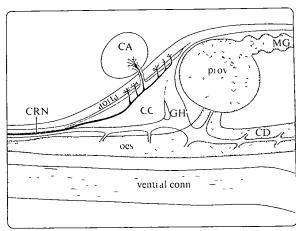
Several surgical experiments (Table 1) were performed as previously described[8], except that the use of Ringer was avoided Close proximity of the functional elements (Fig 1) makes it impossible to settle the matter by a single surgical experiment Cardiacectomy involves removal of the aorta wall adjacent to the CC, which contains axon terminals of the medial neurosecretory brain cells (MNC) Extirpation of the MNC, which seems to cause hyperglycaemia, inevitably injures adjacent tissue, and if nerves controlling the CC were affected, the effect might be caused by uncontrolled secretion of CC hormone This possibility, however, is eliminated by the fact that hyperglycaemia also occurred after the CC had been removed A similar effect results from severing of the cardiacrecurrent nerve (CRN) This operation inactivates the CC (refs 2 and 3), but it also prevents the release of brain hormone by interrupting the pathway to the neurohaemal organ (Fig 1) Cutting of the ventral nervous connective is without significant effect, whereas allatectomy results in a slight hyperglycaemia within 20 h


Fig 1 Position of the main elements of the central nervous system and the neuroendocrine system in the blowfly, together with the anterior part of the aorta and of the alimentary canal with crop and crop duct The retrocerebral endocrine complex (inset) illustrated as a simplified diagram below B, Brain, TG, thoracic ganglion, CRN, cardiac-recurrent nerve, CA, corpus allatum, CC, corpus cardiacum, GH, hypocerebral ganglion, oes, oesophagus, MG, midgut, prov, proventriculus, CD, crop duct, MNC, medial neurosecretory brain cells The main axis of the central nervous system, brain–ventral connective–thoracic ganglion, is severed by decapitation, as is the main axis of the neuroendocrine system, brain neurosecretory cells–CC–aorta wall–CA, since the CRN is severed This compound nerve contains both neurosecretory and non-neurosecretory axons, the latter belonging to the stomatogastric nervous system Axons from the MNC of the brain (aldehyde fuchsin positive) penetrate the CC (ref 6) to terminate in the aorta wall dorsal to the CC This region is their neurohaemal organ Some MNC axons, however, enter the CA in adults[7]

Table 1 indicates that the extreme hyperglycaemia is unlikely to be caused by any hyperglycaemic factor, from the ventral nervous axis or from the neuroendocrine axis Rather, hyperglycaemia occurs after elimination of secretion, either of a brain hormone or CC hormone or both, and so seems to be caused by the lack of a depressing factor The CC produces a hyperglycaemic hormone[1-3,5,9] The other possibility, that a brain hormone, transported to its neurohaemal organ near the CC by way of the CRN, has a hypoglycaemic function,

Table 1 Haemolymph trehalose level given as g l⁻¹ ± s e m before and after various surgical experiments on adult male and female blowflies

	Trehalose average $(g \, l^{-1})$	n	Significance t test
Female blood, before operation	27 5 ±0 92	45	
Male blood, before operation	26 4 ±1 22	60	
Pooled female and male before operation	26 8 ±0 80	105	
Pooled female and male before operation*	26 1 ±1 40	9	
MNC extirpated, 20 h after operation	63 6 ±3 67	8	$P < 0\,001$
Cardiacectomised, 20 h after operation	49 9 ±4 07	9	$P < 0\,001$
CRN severed, 20 h after operation	53 7 ±3 24	29	$P < 0\,001$
CRN severed, 24 h after operation*	56 9 ±7 60	9	$P < 0\,001$*
Allatectomised, 20 h after operation	36 6 ±1 96	42	$P < 0\,001$
Ventral nerve cut, 20 h after operation	22 7 ±2 83	8	$P \sim 0\,1$

Samples from operated flies fed sugar and water only compared with pooled ($n = 105$) samples taken from females and males before operation (then 6 d old)

* Flies (3d old at operation) fed both meat, sugar and water before and during the 24 h before second blood sampling They were treated separately for t test (difference between first and second blood samples)

seems likely, also in view of the ability of MNC extracts to revert the hyperglycaemia (Table 2)

The moderate hyperglycaemia produced by allatectomy may fit with observations indicating that the CA positively regulates the MNC (refs 10 and 11) When allatectomised adults were treated at the time of operation with *Cecropia* juvenile hormone (JH), applied topically on the abdominal cuticle, a trehalose concentration of only 7 5 g l⁻¹ (±2 71 s e m, $n = 9$) was found 20 h later When JH had been applied 10 h after the operation, a trehalose level of 16 3 g l⁻¹ (±1 58 s e m, $n = 8$) was observed after another 10 h Application of JH to ten non-allatectomised flies did not, however, affect blood trehalose concentration

ever, normally derives from ingested sugar (sucrose) rather than from net fat body glycogen conversion to trehalose Nine flies were given water but not sugar from emergence, and 12 h later the CRN was severed At that time the blood contained 17 7 g l⁻¹ trehalose (±0 72 s e m) Blood samples taken 24 h after the operation, during which period they were still given water only, contained 13 0 g l⁻¹ trehalose (±1 10 s e m) They were then given sugar *ad libitum* and in 24 h the blood trehalose level then increased to 44 3 g l⁻¹ (±2 70 s e m)

In mosquitoes the MNC have been shown to regulate glycogen and fat synthesis[14,15] In *Calliphora* deprived of their MNC, the fat body cells contain much glycogen but only little fat[8], and the same seems to hold for fat body cells after

Table 2 Effect of brain extracts (with and without MNC) on flies rendered hyperglycaemic by previous severing of the cardiac-recurrent nerve

	Trehalose average $(g \, l^{-1})$	n	Significance t test
CRN severed, 22 h after operation	52 3 ±3 21	16	
2–3 h after injection of MNC extract	27 8 ±9 66	8	$P < 0\,02$
2–3 h after injection of brain extract	51 2 ±7 02	7	

Each of 16 hyperglycaemic recipients was injected with a crude, freshly prepared extract (homogenate) in Ringer (made by means of a small Potter–Elvehjem type homogeniser) of either three groups of MNC from 7-d-old donors ($n = 8$) or of a similar amount of brain tissue from the same donors, not containing MNC ($n = 7$, 1 died)

In adults the neuroendocrine system is geared to make a relatively high concentration of blood trehalose available at the onset of flight This may partly be caused by a low activity of the MNC In larvae, in which high activity of the MNC and of the CA is linked with developmental events, the trehalose level would consequently be expected to be lower Indeed, in Dipteran larvae including *Calliphora*[12], trehalose has been reported to be very low or absent[13] Preliminary analyses of trehalose concentrations showed 0 5–3 5 g l⁻¹ ($n = 6$) in second instar larvae, 2 8–10 2 g l⁻¹ in third instar larvae ($n = 9$), and up to 16 g l⁻¹ in pupae ($n = 5$) Haemolymph trehalose was also determined in different developmental stages of the butterfly *Pieris brassicae* (Table 3) Again, the more active the MNC and the CA are known to be, the smaller is the content of trehalose in the blood

Hyperglycaemia could be induced both in sugar-fed flies and meat-fed flies (Table 1) Increased blood trehalose, how-

severing the CRN Thus, lipid catabolism may be accelerated as in diabetic vertebrates

Hyperglycaemia was associated with blood hyperosmolarity ranging from 600–1200 mosmol (normal osmolarity 350–400 mosmol) This may be the cause of the polydipsia which developed on removal of the MNC or cutting the CRN within 10–12 h the flies increased in weight from the normal 65–75 mg up to 130 mg Extreme bloating resulted not only from distension of the crop, but also be increased haemolymph volume Such polydipsia in blowflies has been described[8,16], but bursting at weak points of the cuticle often occurs during the night, and so may have passed unnoticed In fact much blood is lost and by continued polydipsia haemolymph composition must be greatly disturbed This, together with the hypertonicity, is bound to have harmful effects on most tissues Since several abnormalities, which seem to result from lack of brain hormone, at least superficially resemble diabetic conditions in vertebrates, it was tempting to test whether insulin had any effect in blowflies (Table 4) No interpretation seems warranted until more knowledge of the endocrine system in blowflies has been obtained and it should be added that no significant effects of injection of insulin into normal intact flies has so far been found

In conclusion, it is suggested that MNC have an important role in the regulation of carbohydrate metabolism When they are removed or prevented from secretion, hyperglycaemia ensues, accompanied by blood hypertonicity, polydipsia, lipid catalysis and fatigue (decreased and slow locomotor activity, perhaps resulting from impeded uptake of trehalose by the muscles) These effects should be related to other findings on

Table 3 Haemolymph trehalose (g l⁻¹ ± s e m) at different developmental stages of the butterfly *Pieris brassicae*

	Trehalose average $(g \, l^{-1})$	n
Third instar larvae	12 5 ±1 39	7
Fifth instar larvae	16 9 ±0 49	7
Non-diapausing pupae	14 5 ±2 17	8
Diapausing pupae	32 4 ±1 13	9
Adults	29 7 ±4 17	9

Diapausing pupae (MNC resting) contain significantly ($P < 0\,001$) more trehalose in the blood than non-diapausing pupae, in which the MNC are active

Table 4 Effect of injecting 500–800 IU kg⁻¹ crystalline ox insulin (insulin) or zinc protamin insulin (ZPI) into hyperglycaemic flies (CRN previously severed)

	Trehalose average (g l⁻¹)	n alive	n died
CRN severed 24 h earlier	53 5 ±3 65	20	
18 h after injection of insulin	23 6 ±5 28	7	1
18 h after injection of Ringer	57 1 ±5 45	8	4
3 h after injection of insulin	41 5 ±4 37	5	
15 h after injection of ZPI	37 8 ±5 87	7	
3 h after second dose of ZPI	29 6 ±4 28	7	

Calliphora-Ringer (1 µl) containing insulin, or Ringer alone (1 µl) was injected after the removal of superfluous blood For about a minute after the insulin injection there were convulsions of the somatic musculature, and increased locomotor activity continued for up to 20 min Otherwise, insulin and ZPI were well tolerated, and the mortality on the second day after severing the CRN was generally lower than in non-treated flies (of which 20–30% died on the second day) The trehalose level before injection was only determined for the first 20 flies (the first experiment and control), since the average value remained close to that in Table 1 (CRN severed)

MNC function and unless MNC hormone(s) has a diversity of functions, it should be determined which effects are secondary to which, when results of MNC extirpation are considered

tibility to these carcinogens We report here results which may provide an explanation for this difference and also for the observation that large doses of dimethylnitrosamine are carcinogenic to the kidney while small doses are not

The major product of the reaction with DNA of metabolites derived from nitrosamines is 7-alkylguanine but other sites are also attacked—alkylation of the O^6 and 3 positions of guanine, the 3 position of cytosine, the 3 and 7 positions of adenine and the O^4 position of thymine have been detected[6-8] O^6-Alkylguanine, in particular, has been shown to miscode and is therefore potentially mutagenic[9,10]

Fig 1 Formation and subsequent loss of 7-methylguanine (7-MeG) from rat kidneys (*a* and *c*) and liver DNA (*b* and *d*) after administration of dimethylnitrosamine Female Wistar rats (160 g) were treated with either 2 5 mg per kg body weight (*a* and *b*) or 20 mg per kg body weight (*c* and *d*) of ¹⁴C-dimethylnitrosamine (DMN) (specific activity 28 mCi mmol⁻¹ and 4 mCi mmol⁻¹, respectively, prepared as previously described[4]) At various times after the injection, DNA was isolated from kidney and liver[4], hydrolysed in 0 1 N HCl (refs 7 and 11) and the liberated purines separated by column chromatography on Sephadex G10 or Dowex-50 (refs 7, 8 and 11) The amounts of 7-methylguanine and O^6-methylguanine present were determined from the radioactivity in the fractions corresponding to the positions of authentic unlabelled markers, the amount of guanine present was determined from the absorbance of the guanine fractions The results are expressed as the proportion of guanine methylated at the 7-position (7-MeG) to total guanine (G) present

Effect of dimethylnitrosamine on persistence of methylated guanines in rat liver and kidney DNA

DIMETHYLNITROSAMINE IS a potent carcinogen in many species, inducing tumours of the liver, kidney and lung[1,2] It is now well established that the carcinogenic activity of this compound is caused by its metabolic transformation within susceptible tissues to a chemically reactive agent which methylates a variety of cellular macromolecules[1-3] In spite of the fact that metabolism of dimethylnitrosamine is eight times greater in the liver than in the kidney, thus the alkylation of macromolecules is eight times greater in liver than kidney, a single large dose of dimethylnitrosamine given to the adult rat induces tumours of the kidney but not of the liver[1,4] (Liver tumours are produced in the adult rat only if dimethylnitrosamine is given after partial hepatectomy[5] or by repeated small doses or prolonged feeding[1,2]) Similar experiments with certain nitrosamides have shown that although they penetrate and subsequently react to alkylate cellular components to a similar extent in many tissues, they do not produce an equal incidence of tumours in all these organs[1-4] It seems therefore, that different tissues vary quantitatively in their inherent suscep-

Further, when a range of alkylating carcinogens of different potency are compared, the ability to form this product correlates much better with the carcinogenicity than the ability to form 7-alkyldeoxyguanosine or the other minor products described above[3,7,11] One possible explanation for the greater sensitivity of the kidney than the liver to a large single dose of dimethylnitrosamine would be any difference in the ability of the tissues to repair lesions produced in DNA before cell division We have therefore studied the persistence of O^6-methylguanine and 7-methylguanine in DNA of rat liver and kidney after a large dose (20 mg per kg body weight) of dimethylnitrosamine which would produce some kidney tumours and a small dose (2 5 mg kg⁻¹) which would not and have found a marked difference in the rate of removal of O^6-methylguanine from the kidney DNA These results may have considerable importance in determining the tissue specificity of tumour production by nitroso compounds and provide further support for the recent hypothesis[12] that the rate of elimination of O^6-alkylguanine from DNA may be an important factor in neoplastic transformation by alkylating carcinogens

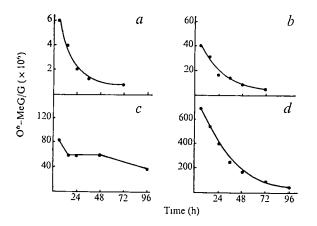
After a dose of 20 mg kg⁻¹ dimethylnitrosamine, the 7-methylguanine formed in liver and kidney DNA was lost at a rate corresponding to a half life of about 60 h (Fig 1) A similar rate of loss was found in kidneys of rats treated


Fig. 2 Formation and subsequent loss of O⁶-methylguanine in rat liver and kidney DNA after administration of dimethylnitrosamine Proportion of guanine methylated at the O⁶ position (O⁶-MeG) to total guanine (G) present in DNA Experimental procedure as in Fig 1

with 2 5 mg kg⁻¹ but the rate of loss in the liver was slightly slower after this dose These data are in reasonable agreement with those published[8,13-15] for various doses and shows that 7-methylguanine is lost from DNA *in vivo* at a rate somewhat faster than that expected from chemical depurination at neutral pH (ref 16) The possible contribution to this loss from the necrosis of highly alkylated cells and dilution by new DNA synthesis could not be determined accurately, however, and it is therefore not possible to determine to what extent an enzymic excision mechanism contributes to the removal

Similar data for the formation and loss of O⁶-methylguanine are shown in Fig 2 In both tissues shortly after administration of the carcinogen the amount of O⁶-methylguanine formed was only about 10% of the amount of 7-methylguanine O⁶-methylguanine in DNA is chemically stable at neutral pH (refs 8 and 17) but this product was lost from the DNA of liver after either dose with a half life of about 20 h This is much faster than the loss of 7-methylguanine and therefore could not have resulted from cell death or DNA replication, which would affect both products equally Clearly, an enzyme system not yet characterised is responsible for the removal A similar system must also be present in the kidney, since O⁶-methylguanine was lost from the kidney DNA after the low dose of dimethylnitrosamine at a rate only slightly slower than in the liver After the larger dose, however, there was a striking difference between the two tissues in the persistence of O⁶-methylguanine in DNA In the liver (where neither the large nor the small dose is effective in inducing tumours) O⁶-methylguanine was lost from DNA at a similar rate after both doses, but in the kidney after the large dose (which does induce kidney tumours) there was an initial fall of about 30% in the amount of O⁶-methylguanine present in DNA between 6 and 15 h after giving the nitrosamine, but there was practically no decline for 50 h and only a slow rate of loss after this period (Fig 2)

Thus the potentially mutagenic O⁶-methylguanine is much longer-lived in kidney DNA after a large dose of dimethylnitrosamine than after a smaller dose or in liver DNA after either dose This correlation with the induction of tumours, together with recent data showing that the brain, which is much more sensitive than the liver to the carcinogenic activity of nitrosamides, is much less active than the liver in catalysing the removal of O⁶-alkylguanine from DNA (refs 12 and 18), provide support for the hypothesis that the differing susceptibilities of organs towards carcinogenic stimuli may be determined by the ability to repair certain alterations produced by the carcinogen in DNA This

ability seems to vary both from tissue to tissue and with the dose of carcinogen used It is not yet known why the loss of O⁶-methylguanine from kidney DNA is so much slower after the larger dose of dimethylnitrosamine, but it is possible that the enzyme system responsible for the removal is somehow inhibited by the large dose of the carcinogen or alternatively, has only a limited capacity to remove this product Further experiments to study these possibilities and characterise the enzymic reactions involved are in progress This process may involve a similar activity to that recently demonstrated in microorganisms[17,19]

Base changes in the recognition site for *ter* functions in lambdoid phage DNA

THE DNA of bacteriophage λ is a linear duplex of about 45,000 base pairs with single-stranded projections of twelve bases at its 5′ termini[1,2] These projections are of complementary base sequence[3] and result from the action of a λ gene product[4], *ter*, on a concatenated form of the phage DNA[5] The base sequences of the single-stranded regions have been determined from repair reactions with DNA polymerase and radioactively labelled nucleoside triphosphates[3] and from analyses of DNase digestion products from 5′-terminally labelled DNA[6] The 3′ terminal sequences of λ DNA have also been determined by analysis of DNase digests of DNA labelled at or near its 3′ termini in exonuclease-repair reactions with T4 DNA polymerase[7] Together, these results gave a sequence of 25 base pairs in the region of the DNA molecule at which the *ter* function interacts (*cos*) The sequence between the nicks that the *ter* enzyme would be required to make in the concatenated DNA is bisected by an axis of twofold rotational symmetry This sequence provided an example of discontinuous or hyphenated symmetry in a DNA sequence recognised by a protein[7] The base sequences of the *lac* operator[8], the λ promoter[9], and the promoter[10] for tRNA$^{Tyr}_{suIII}$ also contain hyphenated elements of symmetry

Of the sixteen base pairs confined between the limits of the symmetrically disposed base pairs, twelve are symmetrically arranged about the axis The classical biochemical genetic approach would define the bases essential for recognition by the *ter* system as those that cannot be changed without leading to

loss of function. Mutations of essential bases in the recognition sequence would thus be effectively lethal, whereas mutations of inessential bases could not be detected readily. Comparison of sequences from different lambdoid phages whose *ter* systems could cross react might well provide information equivalent to that from a series of mutants. We therefore analysed the 5′ terminal sequences of DNA from several other lambdoid phages[6], some of which had *ter* systems that were known to cross react[11]. The DNA from four of these (φ80, 82, 424 and 21) had terminal sequences identical to those of λ DNA, but we report here the 5′ terminal sequences of DNA from another lambdoid phage[12], φD326, which is closely related to φ80. The sequences differ in two nucleotides from the equivalent sequences in λ DNA.

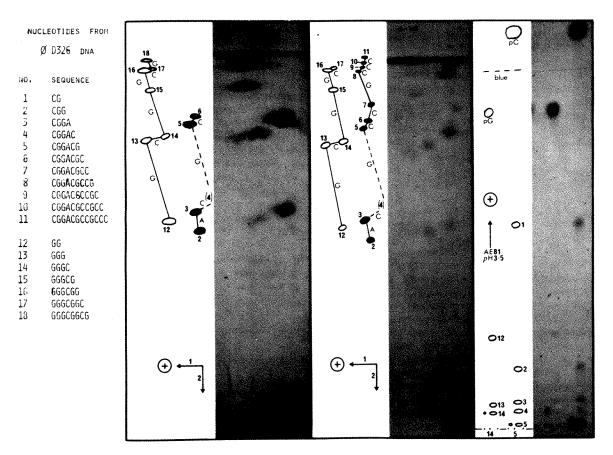
The 5′ terminal sequences of φD326 DNA were determined by the method used previously for several phage DNA preparations. DNA was extracted from the purified phage by treatment with phenol, dephosphorylated with bacterial alkaline phosphatase, and labelled at its 5′ termini with ^{32}P using the polynucloetide kinase reaction. The labelled DNA was purified and digested with pancreatic DNase and the oligonucleotides fractionated by ionophoresis on AE81 and DE81 ion-exchange papers[13], and by two-dimensional ionophoresis on cellulose acetate and thin layer chromatography on PEI cellulose[14] (Fig. 1). The base sequence of each radioactive oligonucleotide was determined from ionophoretic analysis of its products on partial digestion with venom phosphodiesterase. The sequences deduced (Table 1) for the cohesive ends of φD326 DNA are


Fig. 1 Nucleotide maps of DNase digests of terminally labelled DNA from φD326. Stocks of the phage were prepared as described previously[12] and purified by two cycles of equilibrium centrifugation in CsCl (41.5% w/w). DNA was isolated from the dialysed phage preparation by rolling gently with freshly distilled phenol (three times) and was dialysed against four changes of 0.01 M Tris-HCl, *p*H 8.0, 1 mM EDTA. Terminal phosphate groups were removed with bacterial alkaline phosphatase (Whatman, UK; 25 μg ml⁻¹ (2 h at 37 °C)) which was then eliminated by further extraction with phenol and the preparation dialysed against 0.02 M tris-HCl, *p*H 7.5. Labelling with polynucleotide kinase from *Escherichia coli* B infected with phage T4 and γ-^{32}P-ATP (specific activity, 14.8 Ci mmol⁻¹; Radiochemical Centre, Amersham, UK), and purification of the labelled DNA by sedimentation through 6–20% w/v sucrose gradients were carried out as described previously[6,13]. The DNA (170 μg, 73,000 c.p.m, Cerenkov counts [16]) was divided into five portions for digestion with pancreatic DNase in 0.01 M Tris-HCl, *p*H 7.5, 5 mM MgCl₂. Two portions were digested at DNase concentrations of 25 μg ml⁻¹ (37 °C, 3 h) and the products fractionated by ionophoresis on AE81 paper at *p*H 3.5 or DE81 paper at *p*H 2.0 to give oligonucleotides 1–5 and 12–16 the sequences of which were determined from analyses of partial digests with snake venom phosphodiesterase (Table 1). The remaining three portions of the terminally labelled DNA were digested with the same enzyme under milder conditions (2–10 μg DNase ml⁻¹; 60–90 min at 23 °C) and fractionated by ionophoresis on cellulose acetate at *p*H 3.5 (in 7 M urea) followed by transfer[17] to thin layers of PEI-cellulose (Macherey Nagel AG, Germany) for development in 1.6 M formic acid adjusted to *p*H 3.6 with pyridine[14]. The oligonucleotides were eluted with 30% v/v triethylamine carbonate and allotted to their respective family on the basis of the 5′ terminal mononucleotide identified by ionophoresis on AE81 paper, *p*H 3.5, after complete digestion with venom phosphodiesterase[13] (0.1 mg ml⁻¹ in 0.02 M Tris-HCl, *p*H 8.5, 37 °C, 1 h). In the drawings accompanying the photographs, oligonucleotides with a 5′ G terminus are shown as open rings and those with a 5′ C terminus as filled rings. The sequence of oligonucleotides 2–6 and 12–16 was inferred from their behaviour on the two-dimensional system and confirmed by ionophoretic analysis of partial digests with venom phosphodiesterase.(Table 1) on AE81 paper at *p*H 3.5; examples of these on oligonucleotides 5 and 14 are included on the right of the figure. (Oligonucleotide 4 was obtained from the DNase digests fractionated by ionophoresis on AE81 and DE81 papers and was found in partial digests of oligonucleotides 5 to 9 with venom phosphodiesterase, but it was not found in the milder DNase digests analysed two-dimensionally. Its position on the two-dimensional nucleotide maps, shown in parentheses, has therefore been estimated from the difference in base sequence of nucleotides 3 and 5 and the effects on ionophoretic and chromatographic behaviour resulting from addition of C and G residues to oligonucleotides generally[18,19].) The sequence of the longer oligonucleotides was deduced from their behaviour on the two-dimensional separation system, as changes in position are diagnostic of the nucleotide by which two immediate homologues differ[6,18,19] (these are indicated alongside the lines joining the oligonucleotides from the two 5′ terminal families in the drawings to the left of the photographs) and from the necessary complementarity of the two terminal sequences. The different extents of digestion of the two termini of the DNA in the samples shown above is probably fortuitous.

Table 1 Analysis of nucleotides separated by two-dimensional ionophoresis and thin-layer chromatography

Oligonucleotides have been grouped to show the families of progressively overlapping sequences from each 5' terminus of the DNA. Their number refers to their identity in Fig. 1. Mobilities on AE81 paper (*p*H 3.5) and on DE81 paper (*p*H 2.0) are expressed as ratios of the distance moved by the oligonucleotide to that of the blue dye, xylene cyanol FF, and in most cases are the average from several independent experiments. The sequence of each oligonucleotide was deduced from its mobilities and the M values[13,15] of the products of partial digestion with snake venom phosphodiesterase, when each oligonucleotide gave the successively smaller members of its family (Fig. 1). Partial digests of the oligonucleotides (0.01 mg ml[-1] venom phosphodiesterase in 0.02 M Tris-HCl, *p*H 8.5, 20 μl; 23 °C, 20 min and 60 min) were analysed by ionophoresis on AE81 paper at *p*H 3.5 or DE81 paper at *p*H 2.0 (ref. 13).

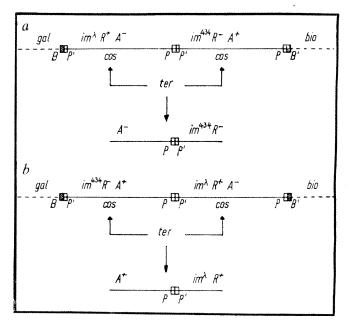
Fig. 2 The 5' terminal sequences of φD326 DNA. The longest oligonucleotide sequences deduced (Fig. 1) have been base-paired and extended by addition of the complementary bases to show the double-stranded structure that would be formed by cohesion of the two single-stranded ends.

written as a base-paired structure in Fig. 2. This structure, like that of the cohesive ends of λ DNA possesses a twofold rotational symmetry; the symmetrically disposed bases are shown enclosed in boxes. The two bases in which this sequence differs from the corresponding region of λ DNA are underlined and both changes are in non-symmetrical positions.

The difference between terminal nucleotide sequences of φD326 DNA and λ DNA could reflect a different sequence requirement for the φD326 *ter* system, or it could indicate that the bases in these positions are unimportant for the *ter* interaction. If the φD326 *ter* system can recognise the appro-

priate nucleotide sequence in λ DNA it should excise λ from a tandem dilysogen. To test this, we followed the genetic approach by which Mousset and Thomas demonstrated the existence of the λ *ter* system.

*Rec*A strains lysogenic for λ*imm*^λ*A*^− and λ*imm*^434^*R*^− (strains *a* and *b* in Fig. 3) were constructed. On the prophage map the *ter* recognition sequence, *cos*, is between the λ genes *R* and *A* and the order of the prophages is defined by the finding that superinfection with the heteroimmune phage λ*imm*^21^ excises λ*A*^−*imm*^434^*R*^− phages from strain (*a*) and λ*A*^+*imm*^λ*R*^+ phages from strain (*b*) (ref. 4). Since the λ site-specific recombination system, *int*, can excise phage λ from a λ dilysogen[4], the heteroimmune superinfecting phage chosen was an integration defective phage (λ*biol*). Phages φ80 (ref. 23) and φD326 (ref. 12) do not integrate at the λ attachment site and therefore have *int* systems with different specificities from that of λ. Phages φ80 and φD326 have the same *int* specificity (N.E.M., unpublished) and since φ80 *int*^+ and *int*^− phages were found to be

Table 2 Heteroimmune superinfection of the λ*imm*^λ−*imm*^434 dilysogens


Superinfecting phage	Relative yields of phage with immunity of either prophage	
	Strain (*a*)	Strain (*b*)
λ*imm*^21*biol*	100*	100†
φ80	46*	61†
φD326	45*	99†
—	1	1

* Over 90% of the phages were λ*imm*^434*R*^−*A*^−
† Over 90% of the phages were λ*imm*^λ*R*^+*A*^+
The results are the average of two experiments. The dilysogenic strains were grown at 32 °C and superinfected with heteroimmune phage at a multiplicity of between 3 and 5, as described by Thomas[24]. Following superinfection with λ*imm*^21 the lysates were assayed on the *sup*II host W1485 (λ*imm*^21*Aam*32*Ram*54*am*60) and following superinfection with either φ80 or φD326 on W1485 (φ80). φ80 and φD326 are homoimmune[12]. The plates were incubated at 38 °C so that the λc1857 plaques (that is λ*imm*^λ) were clear and the λ*imm*^434 plaques turbid. Plaques were purified on the *tonA sup*II strain and tested on a *tonA sup*⁰; *tonA* strains are resistant to φ80 (ref. 23) and φD326 (ref. 12). Media and methods were as described previously (ref. 25). φD326 plaques are always variable in size, presumably because this phage adsorbs inefficiently to its host. Since λ*imm*^434*R*^−*A*^− plaques are extremely small, those excised and therefore packaged by φD326 are very difficult to estimate. This probably explains the relative yield of 45% from strain (*a*) as opposed to 99% from strain (*b*).

Fig. 3 Structures of the dilysogenic strains used. The bacterial host was the *recAsup*II strain QR48 lysogenised by λ*imm*^λc1857*Aam*32 and λ*imm*^434*Ram*54*am*60. B.P′, P.P′ and B′.P are the components of the attachment regions[21]. The markers *A* and *R* are closely linked in the prophage map but are at opposite ends of the vegetative map[22]. The *ter* function acts at *cos* and breaks the linkage between *A* and *R*.

equally efficient in excising phage from λ dilysogens, we felt justified in using the efficiencies with which the *int⁻* phage λ *bio1imm*[21] and the *int⁺* phages φ80 and φD326 excise phage λ from the two dilysogenic strains as an index of *ter* activity.

The results (Table 2) show clearly that phages λ, φ80 and φD326 can all supply a function able to excise linear chromosomes terminated by genes *A* and *R* from a structure in which these termini are linked. We conclude that the *ter* function of φD326, like that of φ80 (ref. 11), is able to act not only on its own *cos* sites but on those of phage λ, even though in this case the *cos* sequences differ in two base pairs from those of φD326.

Since the φD326 *ter* system is able to recognise the appropriate nucleotide sequence in λ DNA as well as in its own, the nucleotides in which the terminal sequences of these two DNAs differ cannot be essential for physiological function. Both nucleotide changes occur at positions that are not included in the symmetrically disposed locations. The observed results are therefore consistent with the hypothesis that the symmetrically arranged bases constitute the recognition element of the target sequence for the *ter* system, but they do not, of course, prove this.

We thank Sandra Bruce and Janet Brown for technical assistance. This work was supported in part by the SRC (UK) and the Swedish MRC.

Plasmid-determined antibiotic synthesis and resistance in *Streptomyces coelicolor*

IN eubacteria, many characteristics[1-3] including resistance to antibiotics and other agents are plasmid-determined. In streptomycetes there are indications that plasmid genes are involved in the production of certain antibiotics: kasugamycin and aureothricin by *Streptomyces kasugaensis*[4], oxytetracycline by *S. rimosus*[5] and turimycin by *S. hygroscopicus*[6]. An increased proportion of antibiotic non-

producing strains is found after treatment of antibiotic producers with agents known to cause plasmid loss in eubacteria; in *S. rimosus,* crosses provided additional evidence that extrachromosomal genes are involved in antibiotic production. In all three species, the cause of antibiotic non-production, for example whether it involved an interruption of the biosynthetic pathway or a defect in the liberation of antibiotic into the medium, was unknown. We report here that both the production of and resistance to the same antibiotic in *S. coelicolor* A3(2) are determined by genes borne on the plasmid SCP1.

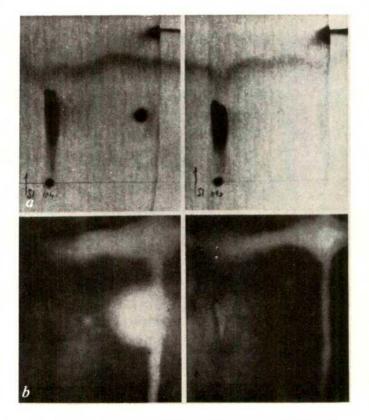
In *S. coelicolor* A3(2) recombination has been used to map more than 100 genes, identified by auxotrophic, resistance and morphological mutations, to a single circular linkage group[7]. Recombination requires cellular contact and leads to the inheritance from each parent of large chromosomal regions; it thus has at least some of the characteristics of conjugation in the Enterobacteriaceae. Moreover, at least part of the exchange of chromosomal markers between mating strains is determined by a plasmid, SCP1. Genetic evidence for the existence of SCP1 is very strong: first,


Fig. 1*a*, Two-dimensional chromatography on silica gel thin-layer plates (Eastman Chromagram No. 13181) impregnated with fluorescent indicator of broth concentrates from cultures of (left) SCP1⁺ strain 104 of *S. coelicolor* A3(2) and (right) SCP⁻ strain 1190. Solvent 1 (run bottom to top in the photograph) was tertiary butyl alcohol–acetic acid–water (72:3:25); Solvent 2 (run left to right in the photograph) was ethyl acetate–acetic acid–water (88:6:6). The chromatograms were photographed in 254 nm ultraviolet light. Note the spot of ultraviolet-absorbing material with R_f 0.45 in Solvent 1 (purer material normally runs at 0.75–0.85) and R_f 0.85 in Solvent 2 in the SCP1⁺ chromatogram. *b*, Bioautography of the chromatograms shown in *a*. Chromatograms were laid on a basal layer of nutrient agar in a 23 × 23 cm Bio-Assay plate (A/S Nunc, Roskilde, Denmark) and overlaid with molten nutrient agar containing *Bacillus mycoides* (3 ml of late log-phase culture per 100 ml agar) and 0.0012% 2,3,5-triphenyl tetrazolium chloride. The plate was incubated overnight at 36 °C. Note the zone of inhibition of *B. mycoides* by the ultraviolet-absorbing spot in the SCP1⁺ chromatogram (left). Nonspecific inhibition by material accumulating at the solvent fronts is present in both preparations.

strains apparently having the plasmid in the autonomous state (SCP1$^+$) transfer the SCP1$^+$ characteristics independently of chromosomal markers ('infectiously') to SCP1$^-$ strains[8], second, SCP1$^+$ strains produce SCP1$^-$ strains with frequencies much higher than those expected of mutations[9], while SCP1$^-$ strains do not revert to SCP1$^+$; third, certain strains, called SCP1' by analogy with F' strains of *Escherichia coli* K12, transfer particular chromosomal genes infectiously, together with the SCP1$^+$ characteristics, to SCP1$^-$ strains[10], as expected if such chromosomal genes have become inserted into the plasmid; fourth, other strains transfer characteristic patterns of chromosomal markers to SCP1$^-$ strains; these are interpretable as having SCP1 inserted into the chromosome at various points[11].

SCP1$^+$ strains (then called IF) were described as producing a diffusible inhibitor that arrested the development of SCP1$^-$ cultures (called UF); SCP1$^+$ cultures were resistant to this inhibitor[8]. We now show that this material is an antibiotic (rather than, for example, a bacteriocin or bacteriophage) and that several genes controlling its biosynthesis, as well as resistance to it, are borne on the SCP1 plasmid.

since it diffuses through dialysis membranes. Two-dimensional chromatography of extracts of culture fluids reveals a single difference between isogenic SCP1$^+$ and SCP1$^-$ cultures: the presence, in SCP1$^+$ preparations, of a discrete ultraviolet-absorbing spot (Fig. 1*a*) which produces a zone of inhibition of the test organism in bioautography (Fig. 1*b*). Antibiotic eluted from this spot inhibited sensitive organisms at concentrations less than 10 μg ml^{-1}.

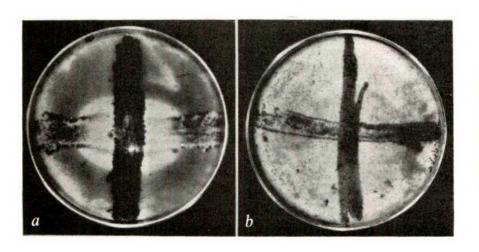
Seven strains carrying SCP1-linked mutations resulting in lack of antibiotic activity were isolated from a strain bearing the SCP1'-*cysB*$^+$ plasmid[10]. They were detected by replica plating colonies to plates spread with SCP1$^-$ spores and occurred, after mutagenesis by ultraviolet (254 nm), or by 365 nm light in the presence of 8-methoxypsoralen[7], with a frequency of about 5 × 10^{-4}. All the mutants retained antibiotic resistance. Most were revertible to antibiotic production, suggesting that they were point mutations. Plasmid linkage of the mutations was demonstrated by transferring the plasmid from each mutant to a *cysB*$^-$ SCP1$^-$ strain, which remained antibiotic negative, while acquiring antibiotic resistance and the extrachromosomal *cysB*$^+$ allele.


Fig. 2 Tests for antibiotic cosynthesis by pairs of antibiotic-negative mutants. Each plate was prepared by inoculating two mutants, by replica plating from master plates, at right angles on a plate sown with spores of an SPC1$^-$ tester strain. *a*, Cosynthesis by R40 (secretor: vertical streak) and R39 (convertor: horizontal streak): a zone of inhibition of the test strain extends from the centre of the plate along the R39 culture. *b*, Lack of cosynthesis by R40 (vertical streak) and R53 (horizontal streak).

When spores of SCP1$^+$ and SCP1$^-$ strains are inoculated close together on agar, both cultures reach a stage immediately preceding aerial mycelium production before antibiotic diffusing from the SCP1$^+$ culture prevents further development of the nearby SCP1$^-$ culture. Production of antibiotic by the SCP1$^+$ culture, rather than susceptibility of the SCP1$^-$ culture to its action, is correlated with the development of aerial mycelium; young vegetative mycelium of SCP1$^-$ strains is susceptible to antibiotic produced by mature SCP1$^+$ cultures as can be shown by placing agar plugs cut from such cultures on plates inoculated with SCP1$^-$ spores. Susceptibility to the antibiotic is not confined to SCP1$^-$ cultures of *S. coelicolor* A3(2); the antibiotic has a wide antibacterial spectrum. About half of a collection of *Streptomyces* spp. was found to be susceptible[12]. Of other actinomycetes and related bacteria, one *Nocardia* sp. was sensitive and two *Mycobacterium* spp. and one *Corynebacterium* sp. were resistant. Members of all Gram-positive eubacterial genera tested were sensitive: *Azotobacter*, *Bacillus* (six species), *Micrococcus*, *Staphylococcus*, *Streptococcus*. One member of each of the Gram-negative genera *Escherichia*, *Klebsiella*, *Salmonella*, *Serratia*, *Agrobacterium*, *Pseudomonas* and *Rhizobium* was resistant, but *Erwinia carotovora* and *Proteus vulgaris* were susceptible. Fungi of the genera *Saccharomyces* and *Penicillium* were unaffected.

The antibiotic is of comparatively low molecular weight,

Pairs of mutants were tested for antibiotic cosynthesis[13] by inoculating them at right angles on plates sown with spores of an SCP1$^-$ tester strain. Positive tests (Fig. 2*a*) indicated secretion of a material without antibiotic activity by one strain and its conversion to antibiotic by the other; the shape of the inhibition zone allowed identification of the secretor and convertor mutants. The simplest explanation is that the mutations are in plasmid-linked structural genes controlling a pathway of antibiotic synthesis, rather than genes indirectly concerned in antibiotic production. Four plasmid-coded biosynthetic steps are indicated by the classification of the seven mutants into four cosynthetic classes; doubtless this is an underestimate of the number of steps in the pathway, although some steps yet to be revealed by mutants may be controlled by chromosomal genes.

The mechanism of SCP1-coded antibiotic resistance is unknown; however, the finding that a *Streptomyces* plasmid codes for synthesis of and resistance to the same antibiotic is interesting in relation to the possible origin of plasmid-borne genes conferring resistance to actinomycete antibiotics in Gram-negative eubacteria. The theory that such genes originated in antibiotic-producing actinomycetes, many of which possess antibiotic-inactivating enzymes analogous with those of plasmid-carrying Gram-negative eubacteria[14], does not require such enzymes to be coded for by plasmids in the producing organisms. But transfer to other genera might have been aided if this were the case, a

possibility made more likely by our results with *S coelicolor*

A second implication of these results is in the evaluation of techniques of gene amplification and other aspects of plasmid manipulation in developing new strains of industrial antibiotic-producing actinomycetes

The β₂-microglobulin gene is on chromosome 15 and not in the HL-A region

POSSIBLE evolutionary homology between the genetic regions controlling histocompatibility antigens (such as HL-A in man and H-2 in the mouse) and immunoglobulins has been proposed[1][2] Recent studies involving β_2-microglobulin (β_2m) seem to support this idea Human β_2m was found originally in the urine of patients with renal tubular dysfunction It is also present in serum and on the surface of most types of cell[3][4] It has a molecular weight of about 12,000 and shows substantial sequence homology with the constant region domains of immunoglobulin heavy chains[5][6] Partially purified papain[7][8] and detergent[9] solubilised HL-A molecules, and H-2 molecules[10], consist of two chains one of which is invariant and has been identified as β_2m[11-13] Chance association during the isolation procedure has been shown to be unlikely by the cocapping on the cell surface of β_2m with the allogeneic chain of HL-A that carries the usual serologically detected determinants[14-16]

The genes controlling the HL-A determinants form part of a complex genetic region associated with immune functions including transplantation rejection, mixed lymphocyte culture stimulation, graft *versus* host response, cell mediated lympholysis, immune response and some complement functions (see ref 17) The possibility that all these functions, which involve the cell surface and its role in recognition, are mediated by molecules evolutionarily related to immunoglobulins might be supported by the location of the gene for β_2m in this region Using the techniques of somatic cell genetics with human–mouse hybrid cells we have, however, shown that the gene for β_2m is not located in the HL-A region

Antiserum to human β_2m produced in rabbits (Dakopatts, Denmark) was active in a cytoxicity assay performed using our standard procedure[18] To remove nonspecific toxicity against mouse cells specially selected rabbit complement was absorbed with the 8-azaguanine L cell derivative 1R, which was the parent mouse cell in most of the hybrids tested

The last dilution of the antiserum which gave a 50% kill in complement-dependent cytotoxicity on primary human fibroblasts was 1/64 The antiserum did not kill the parent

¶¶ The DUR hybrids were made between 1R and a human X/15 translocation fibroblast in which the X/15 chromosome is active Selection in 8-azaguanine resulted in the loss of both chromosome X and 15 markers Further details of the analysis of these hybrids will be published elsewhere

mouse 1R cells but had a titre of 1/32 on a representative positively reacting human–mouse hybrid, HORL9 The specificity of this reaction on hybrid cell lines was checked by absorptions with different cells and with partially purified β_2m Absorption with mixed human type A and O red blood cells[19] (three times with an equal volume), 1R (two times with 2×10^8 cells ml⁻¹) or spleen cells taken from CBA and C3H mice, the strain from which L cells are derived (two times with 5×10^8 cells ml⁻¹) failed to reduce the titre of the antiserum on primary human fibroblasts or the hybrid, HORL9 In contrast, the antiserum's activity on either fibroblasts or the hybrid could be totally absorbed by HORL9 (two times 2×10^8 ml⁻¹), the human lymphoblastoid cell line T51 (2×10^8 ml⁻¹) and 100 μg ml⁻¹ of partially purified β_2m The β_2m (a gift from Professor B Pernis) was prepared from the urine of crash victims, the material showed five equally staining bands by SDS electrophoresis A more highly purified preparation prepared from urine by D Snary and M Crumpton, showing only one major band and two minor bands on SDS electrophoresis, also completely absorbed the antiserum at a concentration of about 20 μg ml⁻¹ On Ouchterlony double diffusion plates both preparations gave a single precipitin line with the Dakopatts antiserum The antiserum absorbed with 4×10^8 1R cells ml⁻¹

gave this precipitin line while absorption with 4×10^8 HORL9 cells ml^{-1} removed it A goat antiserum to human β_2m (Kallestad) gave a reaction of total identity with the Dakopatts antiserum on Ouchterlony plates against partially purified β_2m It also gave identical cytotoxic reactions with the Dakopatts antiserum

The cytotoxicity reactions were confirmed using immunofluorescence 1×10^5 test cells were mixed with 50 μl of a suitable dilution (1/50) of test antiserum, after 30 min the cells were washed three times and suspended in 50 μl of a 1/20 dilution of fluorescein-labelled sheep anti-rabbit IgG (Wellcome) The cells were incubated at 4 °C 30 min, washed three times and mounted in 50% glycerol in phosphate buffered saline on a slide under a sealed coverslip The cells were then scored under a Leitz orthoplan fluorescence microscope fitted with a ploem epiilluminator, a BG12 primary filter, K510 secondary filters and a K495 suppression filter Species specificity in immunofluorescence was only achieved after absorption with 2×10^8 1R cells ml^{-1} Further absorption with 1R or human red blood cells failed to remove any activity on human lymphoid cells or the hybrid HORL9 As in cytotoxicity, the reaction in immunofluorescence could be totally absorbed by the human lymphoid cell T51

The specificity of the anti-human β_2m was further checked by immunoprecipitation of membrane extracts Incubation[20] of chloramine T ^{125}I-labelled deoxycholate-solubilised membranes[21] from a human lymphoblastoid cell line with rabbit anti-β_2m, followed by the addition of horse anti-rabbit IgG, could be used to precipitate a low molecular weight protein of the same size as β_2m, identified on SDS polyacrylamide gels A similar precipitation procedure with mouse spleen cell membranes did not yield this protein It has been suggested that rabbit anti-human β_2m (ref 22) can recognise mouse lymphocytes, causing B cell mitogenesis These authors agree with us, however, that the antiserum is not cytotoxic for mouse cells

The results of testing the anti-β_2m sera by complement-dependent cytotoxicity and immunofluorescence, as described above, on a series of human–mouse hybrids are given in Table 1 The two techniques used gave identical results Work in our laboratory[23] using human–mouse somatic cell hybrids has provided evidence that the genes for mannose phosphate isomerase (MPI, EC 5 3 1 8) and pyruvate kinase 3 (PK-3, EC 2 7 40) can be assigned to chromosome 15 Our study of these and other hybrids, as well as providing more data on this linkage, provides evidence that β_2m is also coded for by a gene on chromosome 15 The origin of most of the hybrids studied and the techniques for their production, propagation and chromosomal analysis were as previously described (see refs in Table 1 and ref 24)

The β_2m positive hybrid HORL9 has only three human chromosomes[24], X, 11 and 15 HORP27R, on the other hand, is an 8-azaguanine-resistant hybrid derivative which lacks the X chromosome, but is β_2m positive On the basis of these data, β_2m must be coded for by a gene on either chromosome 11 or 15 HORL8, however, which lacks chromosome 11 and is β_2m positive excludes linkage to chromosome 11 From Table 1 it can be seen that four primary hybrids with chromosome 15 have β_2m and six primary hybrids lacking chromosome 15 lack β_2m The corresponding subclone numbers are 12 (+ +) and 8 (− −) The only exception to the expression of human β_2m in human–mouse hybrids with chromosome 15 is AD, which comes from a cross of the human lymphoblastoid line Daudi by the mouse L cell derivative A9 (ref 25) This exception agrees with the fact that Daudi does not express β_2m[4], which we have confirmed This suggests that the lack of expression of β_2m in Daudi may be due to a change in the genetic region encompassing the β_3m gene, a possibility which can be checked by analysis of more clones derived from Daudi $\times$ A9 hybrids

The only simple conclusion consistent with these data is that β_2m is coded for by a gene located on chromosome 15 We have obtained further confirmation of this assignment by the use of anti-β_2m and complement to select for hybrids which have lost the chromosome carrying the β_2m gene

It should be noted that the fact that HORL9 absorbs out all the activity of the Dakopatts antiserum on human fibroblasts, together with the lack of reactivity of this serum on hybrids containing human chromosomes X and 11 without 15, is strong evidence for the antiserum recognising only a product of chromosome 15, both on human–mouse hybrids and on normal human cells This product is human β_2m as shown by the absorptions with partially purified β_2m

Population and family studies[26] as well as inter[27] and intraspecific[28] hybrids have been used to assign the complex HL-A region to chromosome 6 The two polypeptides of the HL-A molecule are therefore coded for by unlinked genes This result does not, of course, necessarily imply that the genes for the allogeneic chain of the HL-A molecule are not related to the β_2m gene The light and heavy chain genes of the immunoglobulins, which are evolutionarily related, are unlinked[29] Our data do, however, raise the question of how many genetic regions exist in the human genome whose evolution can be traced to a common ancestry with the immunoglobulin genes The possibility that the immunoglobulin heavy chain genes are linked to the β_2m gene on chromosome 15 has not yet been excluded

It is interesting that none of the hybrids in Table 1 has chromosome 6 nor can they be killed by HL-A antisera in a normal cytotoxicity test Hybrids derived from HORL9 with chromosome 15 as the only human chromosome present can express β_2m, strongly suggesting that human β_2m can be expressed on cells in the absence of the products of the human major histocompatibility region We are now using our hybrids to study the possible interaction between mouse H-2 allogeneic chains and human β_2m In collaboration with R Kennett, we have recently detected HL-A on human–mouse hybrids by direct cytotoxicity and absorption in the presence of human β_2m

Genes required for cytotoxicity against virus-infected target cells in *K* and *D* regions of H-2 complex

EVIDENCE is mounting that in mice, certain specific immunological effector functions of thymus-derived (T) lymphocytes are efficient only when donors of T cells and the cells with which they interact have at least a part of the H-2 gene complex in common[1-8] Examples include T helper function *in vivo* and *in vitro*[1-3], cytotoxicity mediated by T cells against virus-infected[4-6] or TNP-modified[7] target cells *in vitro*, immunopathology mediated by T cells[4], or protection against bacterial[8] and viral infection[6] *in vivo* This requirement for H-2 compati-

bility has been studied in detail by measuring the cytotoxicity of T cells from donors immunised with either lymphocytic choriomeningitis (LCM) or ectromelia virus using target cells infected with the homologus virus

These two viruses are very different, LCM being a non-cytopathic, single-stranded RNA virus which acquires an envelope by budding from infected cell membranes, whereas ectromelia is a cytopathic DNA virus which is assembled completely within infected cells[9] Evidence described in detail elsewhere[4,10,11] indicates that immune T cells kill virus-infected target cells directly by contact without production of detectable soluble factors or any requirement for ancillary cells such as mononuclear phagocytes or thymus-independent (B) cells Experiments with target cells of different H-2 haplotypes and a repertoire of inbred mouse strains, including congenic pairs, have shown that the non-H-2 genetic background, the M locus and H-2 public specificities are irrelevant[4,11] Maximal cytolysis only occurs when immune T cells and virus-infected target cells share the same H-2 haplotype[4,11]

These findings suggest that the genes required are either the H-2 private specificities, which code for the major H-2 antigens on which the haplotype classification is based, or genes closely

linked to them in the *K* and *D* regions of the H-2 complex Identity of *Ir* genes, which map in the *I* region between *K* and *D* (Table 1) and which are common to many different H-2 haplotypes, should not be sufficient[12] This reasoning was tested directly using mouse strains bearing recombinant H-2 haplotypes (Table 1) Immune spleen cells were obtained from donor mice immunised with either LCM virus or ectromelia virus as

described elsewhere[5,11], and specific cytotoxicity mediated by T cells was measured by [51]Cr release from virus-infected target cells of various H-2 haplotypes using optimal spleen cell–target cell ratios[5,11] (Tables 2 and 3) Immune cells almost invariably caused more lysis than normal cells, irrespective of target cell type, but significant specific lysis was defined as occurring only when combinations of immune cells and infected targets gave [51]Cr release which was significantly higher ($P < 0.05$) than all three control combinations, such as immune cells with uninfected targets, or normal cells with either infected or uninfected targets Comparison of Tables 1 and 2 shows that specific lysis of LCM-infected H-2^k target cells required immune T cell donors to be of H-2^k type only in the K or D regions of the gene complex It was not sufficient for all of the I and S region to be k (as in A TL mice) Lysis of LCM-infected H-2^d or H-2^b targets also required only D region homology The use of H-2^s and H-2^q macrophages as target cells confirmed that K region homology was sufficient

Results obtained with ectromelia virus (Table 3) were essentially similar to the LCM system, with one exception Lysis of infected H-2^k target cells by ectromelia-immune cells from C3H OH or C3H OL mice (which are of H-2^k type in the D region) was not as reproducible or powerful as with LCM Ectromelia provoked a significant response against infected H-2^k targets (Table 3) in only one out of three experiments with C3H OH, and one out of two experiments with C3H OL, whereas a significant response always occurred against infected H-2^d targets Thus major gene(s) active in the LCM system seemed less active in the ectromelia system The factors responsible for this variation are not known, but Ir genes are candidates for further investigation

With both viruses, B10 A (2R) gave a small but statistically significant response against H-2^d target cells in one out of two experiments (Tables 2 and 3), suggesting that genes outside the K or D regions (for example, in IC or S regions in this case) may sometimes exert a minor influence

In summary, these data support the concept that the major genes required for cytolysis mediated by T cells, of virus-infected target cells are located in the K or D regions of the H-2 complex In most cases, these genes are sufficient, without the requirement for I region homology Whether Ir genes play a secondary, regulatory role remains to be determined This is consistent with the hypothesis proposed[4,5] that the H-2-dependent restriction of lysis, mediated by T cells, of virus-infected target cells results from T cell recognition of altered self antigens (possibly H-2 private specificities) on the surfaces of virus-infected cells

Evolutionary conservation of H-Y ('male') antigen

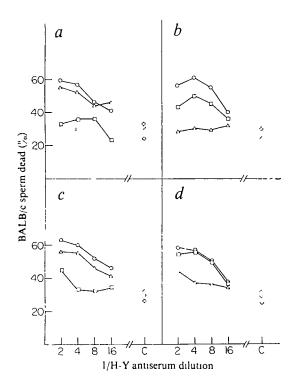
The male specific (H-Y) antigen of mice was discovered with the observation that within certain inbred strains, females reject male skin grafts, whereas skin grafts exchanged between all other sex combinations are accepted[1] (reviewed in ref 2) It is now established that females sensitised with male skin grafts (or immunised with male spleen cells) produce antibody which is cytotoxic for sperm[3] and dissociated male epidermal cells[4] Using the sperm cytotoxicity test and the mixed haemadsorption-hybrid antibody (MHA HA) test, we demonstrated earlier[5] that the H-Y antigen of mice is cross reactive or identical with antigen


Fig 1 Summary of cytotoxicity tests on mouse sperm with mouse H-Y antiserum after absorption with male or female cells from four test species Each point is an average of values from three separate tests (b, chicken and c, leopard frog), four tests (a, mouse) or six tests (d, X laevis) O, Unabsorbed H-Y antiserum, △, absorbed with female cells, □, absorbed with male cells (spleen cells of mouse, blood cells of chicken, spleen and liver cells of amphibians), ◇, control, complement included, antiserum omitted H-Y antisera were prepared in adult C57BL/6 female mice by four to six weekly intraperitoneal injections of 30–60 x 10⁶ C57BL/6 male spleen cells Individual serum samples were tested, diluted one-half and pooled for absorption Cell suspensions for absorption were prepared as follows (1) Mouse spleen, according to Wachtel et al[5] (2) Amphibians spleen and liver were minced in Earle's balanced salt solution (EBSS) and the supernate, containing free cells in suspension, was removed and centrifuged at 100–150g for 10 min The cells were washed twice and resuspended in EBSS (3) Chicken red blood cells and buffy coat leukocytes were collected from whole heparinised blood after centrifugation at 700–800g 10 min Cells were washed twice and resuspended in EBSS All absorptions were carried out on ice for 30–40 min, 1–2 parts serum per 1 part cells Epididymal sperm, prepared from BALB/c mice according to Goldberg et al[3], were incubated with H-Y antisera and with absorbed rabbit serum diluted 1 14 (complement source) for 45–50 min Trypan blue dye was added during the last 5–10 min of incubation and the tests read in a haemocytometer Dead sperm stained with the dye

found in male rats, guinea pigs, rabbits and humans Since then we have extended our survey to classes other than mammals, and we give evidence here for the occurrence of murine H-Y (or a cross reactive) antigen in the white leghorn chicken (*Gallus domesticus*) and in two amphibian species, the leopard frog (*Rana pipiens*) and the South African clawed frog (*Xenopus laevis*)

H-Y antisera were raised in female C57BL/6 mice by immunisation with male C57BL/6 spleen cells as reported

Table 1 Sex association of H-Y antigen

Class	Species	Heterogametic sex	H-Y antigen found in
Mammalia	*Mus musculus**	Male	Male
Aves	*Gallus domesticus*	Female	Female
Amphibia	*Rana pipiens*	Male	Male
	Xenopus laevis	Female	Female

* Mouse

previously[5] For each serological test, the selected H-Y antiserum pool was diluted and divided into three parts (as in our earlier studies[5]) The first part was absorbed with female cells of the species being tested (aliquot A) and the second, with male cells (aliquot B) while the third was not absorbed (aliquot C) The three aliquots were then titrated for residual cytotoxic activity against mouse sperm Absorption of cytotoxic activity from aliquot A or B would indicate that H-Y antibody must have been removed specifically by female (A) or by male (B) cells of the species being tested, signifying that the absorbing cells of this species carry a surface component identical or cross-reactive with mouse H-Y antigen

H-Y antiserum aliquots used in the confirmatory MHA HA tests were prepared and absorbed in the same way The indicator cells, mouse sperm, were then incubated with the three aliquots A, B and C, washed, and subsequently exposed to a rabbit hybrid antibody with the specificity anti-mouse Ig / anti-sheep red blood cells (SRBC) The sperm were again washed and then reacted with SRBC In this assay, sperm which have taken up H-Y antibody, and therefore also the hybrid antibody, bind SRBC to form rosettes Absorption of H-Y antibody from

Table 2 Summary of MHA HA test data reaction of mouse H-Y antiserum with mouse sperm after absorption with cells from male or female chicken or X laevis

| | Serum aliquot | | |
	A (absorbed ♀)	B (absorbed ♂)	C (unabsorbed)
Chicken	14 2*	23 8	25 4
X laevis	7 0	15 9	16 6

To avoid repeated centrifugation, the MHA HA reactions were carried out by centrifuging the sperm through a discontinuous density gradient containing the reagents and wash layers in sequence[5,18] Gradients were established in tubes made from 1-ml disposable glass pipettes by addition of heat-inactivated, gamma globulin-free foetal bovine serum (FBS) The concentration of FBS in each layer was adjusted to prevent intermixing Sperm were obtained from the epididymis of BALB/c mice according to Goldberg et al[3] A sample of 0 05 ml of a suspension containing 5–10 x 10⁶ sperm per ml was reacted with 0 05 ml H-Y antiserum diluted one-half, the suspension of sensitised sperm was then placed in the gradient tube and centrifuged at 35–50g for 10 min and at 150–200g for 10 min The pellet (containing sperm and SRBC) was removed and recentrifuged (35–50g for 10 min) to enhance rosette formation After standing for 30 min on ice, the pellet was resuspended and samples were read in a haemocytometer Three tests each (chicken and X laevis) were scored as coded samples by an observer who recorded the counts of rosettes and free sperm The values (percentages) shown here were derived from the formula number of rosettes / number of rosettes+free sperm Any sperm cell to which three or more sheep red blood cells had adsorbed was scored as a rosette

* Average number of rosettes per 100 sperm cells

aliquot A or B in the MHA HA test is indicated by a decrease in the number of rosettes in comparison with the number observed with unabsorbed antiserum (aliquot C)

In view of existing evidence[6,7] for a sex-associated transplantation antigen in the heterogametic sex of the chicken (which is the female in this case, Table 1) we studied this species first, using both the cytotoxicity and MHA HA tests The results of our experiments (Fig 1, Table 2) indicate that the chicken has an H-Y (H-W) antigen identical or cross reactive with mouse H-Y, and that it is expressed by the female The decrease in cytotoxicity titre produced by absorption with male chicken cells (Fig 1) is not more than what can be attributed to anti-complementary effects of the absorption procedure Such a decrease was not seen in the MHA HA test, which does not depend on complement (Table 2)

Since birds and mammals represent widely divergent pathways of reptilian evolution, we suspected at this point

that H-Y antigen would be found in reptiles, and so we next investigated its possible occurrence in Amphibia, a more primitive class of vertebrates In *R pipiens* the male is heterogametic as in mammals whereas in *X laevis* the female is heterogametic as in birds (Table 1) Our serological tests (Fig 1 and Table 2) demonstrate that cells from both these species contain a surface component identical or cross reactive with H-Y antigen of the mouse Moreover, the antigen is found in the heterogametic sex of both these amphibian species Thus it would seem that the cell surface component conferring H-Y antigenicity in the mouse has been conserved through some 300 Myr of evolution (spanning the Carboniferous radiation of amphibians and the Pleistocene emergence of man)

Although the phylogenetic conservation of a particular polypeptide sequence (indicated here by common antigenicity) suggests some essential or highly advantageous role, the reason for the conservation of H-Y antigen is not at all obvious Nevertheless the association of H-Y antigen with either one sex or the other in those species tested so far seems to indicate a sex-related function of some kind, perhaps one concerned with the recognition of one sex by the other in nature (see discussion by Thomas[8])

As to whether or not H-Y antigen expression is hormone dependent[9], several experiments involving male←→female transplantation and/or hormonal manipulation have given conflicting results[10-16] Sex-limited, hormone-dependent traits affecting the cell surface are known however Indeed the 'Hi' red blood cell agglutinogen of chickens is normally confined to females although this trait can be induced in males by treatment with diethylstilboesterol[17] Thus it seems wise to leave open the question of the extent to which expression of H-Y antigen may be influenced quantitatively by sex hormones, although our finding that H-Y may occur in females implies that its expression is not qualitatively hormone-dependent In this context it remains to be determined whether or not the *H-Y* structural locus is situated on the Y chromosome An exceptional species in which H-Y antigen were found in the homogametic sex would suggest that the *H-Y* structural locus is autosomal (or even X-linked) We are now investigating what may prove to be such an exception

Production of lymphoid tumours in hamsters by direct implantation of normal human leukocytes

LEUKOCYTES from patients with various lymphoproliferative diseases can be serially transplanted as malignant lymphoid tumours in immunosuppressed newborn hamsters[1] We report that normal human leukocytes can also be transplanted into newborn hamsters treated with antilymphocyte serum

Three human leukocyte samples were used, one from peripheral blood of an Epstein–Barr virus (EBV) antibody-positive normal male and two from umbilical cord blood with and without EBV infection Leukocytes were separated by Dextran sedimentation from 20 ml of peripheral or cord blood and $0 5-1 \times 10^7$ viable leukocytes were implanted intraperitoneally into Syrian golden hamsters less than 24 h of age This was followed by twice weekly intraperitoneal inoculation of $0 1$ ml rabbit antilymphocyte serum against hamster thymocytes The leukocytes from cord blood were incubated with 1 ml of a filtered freeze–thaw extract of the (EBV+) B95 cell line[2] at 37 °C for 2 h, before implantation

All three hamsters transplanted with peripheral leuckocytes and two out of three hamsters transplanted with cord leukocytes infected with EBV were found to have lymphoid tumours involving the lymph nodes, liver, lungs and kidneys, when killed on days 11–21 No tumours were observed, however, in hamsters transplanted with cord leukocytes not infected with EBV

Enlarged inguinal lymph nodes resulting from transplantation of peripheral leukocytes or EBV-infected cord leukocytes were cultured in medium RPMI 1640 supplemented with 20% foetal calf serum, and two lymphoblastoid cell lines were established from a hamster of each group The cells began to grow vigorously in about 3–4 weeks and have been maintained for 6 months These cell lines have a normal diploid human chromosome constitution and are positive for EBV nuclear antigen[3] Electron microscopy revealed EBV particles in lymphoid cells

Our observation seems to be analogous with the establishment of lymphoblastoid cell lines *in vitro* from normal human peripheral and cord leukocytes, for which an essential role of EBV has been demonstrated[4,5] Successful heterotransplantation of normal human leukocytes into hamsters may be based on the same mechanism as in the *in vitro* system It is possible that normal human lymphocytes can be transformed *in vivo* by EBV and grow progressively in the immunosuppressed heterologous hosts

This work was supported by a grant from the Japanese Ministry of Health and Welfare We thank Dr Kiyoshi Hiraki for advice and Dr Yorio Hinuma for testing EBV nuclear antigen.

matters arising

Variation of *G*

DEARBORN and Schramm have considered limits on the variation of *G* imposed by the existence of clusters of galaxies and globular clusters of stars[1] Their argument is that if *G* has been varying too rapidly the clusters would have dispersed and we would not see them now They conclude that my theory of the variation of *G*, based on the Large Numbers Hypothesis, is untenable

These authors (and several other workers in the field) have misunderstood the main feature of my theory They work with a Newtonian theory in which gravitational mass can vary independently of inertial mass, so they are adopting a pre-Einstein view of gravitation On such a basis there would be no explanation for the motion of the perihelion of Mercury

The coefficient *G* has dimensions and its value depends on what units one uses One might refer it to standard units of physics, g, s and cm Then the question whether *G* varies depends on how these units are defined and is not a fundamental question of physics One should avoid man-made units and use only those provided by nature One may take units of time and distance provided by atomic clocks and the velocity of light, and a unit of mass provided by an atomic particle, say the proton Referred to such units the variation of *G* has an absolute meaning

If this *G* varies, the question arises of how to fit it into physical theory without destroying the successes of the Einstein theory A natural way of doing that is to suppose that all the laws of classical mechanics, including the Einstein theory, are applicable only when referred to suitable units that differ from the atomic units This is a development of an idea originally proposed by Milne[2], that there are two scales of time that are important in physics

Let us call the units that must be used for the laws of classical mechanics to apply 'mechanical units' For any problem involving dynamical motions and not referring to atomic processes one may work with mechanical units, and the calculations will then not be affected by the variation of *G* referred to atomic units This variation may be ascribed to the variation of the atomic units referred to the mechanical units Thus calculations of the stability of clusters

can throw no light on the variation of *G*

One can obtain evidence about the variation of *G* referred to atomic units by making astronomical observations with atomic apparatus One method is to observe accurately the times of lunar occultations with atomic clocks This method has been used by Van Flandern[3] who has obtained evidence that *G* does vary Another method is to work with I I Shapiro's observations of radar reflected by the planets These are not yet sufficiently accurate to give a definite result, but one can hope that they will be in the near future

Future impact of fossil CO₂ on the sea

WHITFIELD[1] has challenged, on chemical grounds, the conclusion[2-4] that uptake of fossil CO_2 by the sea will eventually lead to unsaturation of calcium carbonate The optimistic conclusion that "serious environmental effects are not likely in the foreseeable future" is unwarranted for the following reasons (1) Whitfield's theoretical analysis obviously fails to maintain equivalence between anions and cations as CO_2 is taken up by seawater This impossible situation means only that the increase in total CO_2 predicted by mixing models is incompatible with the chemistry, changes in the degree of calcium carbonate supersaturation with increasing CO_2 partial pressure (P_{CO_2}) requires further analysis (2) Whitfield assumed too high an initial concentration of total inorganic carbon (ΣCO_2) in seawater, equivalent to $2\,66 \times 10^{-3}$ M We have measured ΣCO_2 in hundreds of samples of surface seawater (ref 5 and A W F, and J L E, unpublished observations) as have Li *et al*[6], which generally falls in the range $2\,05 \pm 0\,05 \times 10^{-3}$ M For an initial seawater ΣCO_2 of 2 05 (pH 8 00) and using MacIntyre's[7] values of the stoichiometric solubility product constants (K_{sp}') of calcite ($10^{-6\,17}$) and

aragonite ($10^{-5\,97}$), the carbonate concentrations for aragonite and calcite saturation are, respectively, $1\,07 \times 10^{-4}$ M and $0\,68 \times 10^{-4}$ M ($Ca^{2+} = 10^{-2}$ M), the corresponding reductions in carbonate are $0\,99 \times 10^{-4}$ M and $1\,38 \times 10^{-4}$ M, respectively The latter is only 60% of the value estimated by Whitfield for his higher ΣCO_2 for seawater (3) The degree of present-day supersaturation of seawater with respect to aragonite and calcite, and how this will change with increasing P_{CO_2}, depend on the choice of the various equilibrium constants of the ionic equilibria involved, about which there is some lack of concensus The degree of supersaturation is expressed by the ratio aCa_{2+} $a_{CO_3}{}^{2-}/K_{sp}$, where K_{sp} is the thermodynamic solubility product constant of $CaCO_3$, the *a*s are ionic activities γM, (where γ is the ion activity coefficient) Berner[8] measured γCa^{2+} to be around $0\,21 \pm 0\,01$, and $\gamma_{CO_3}{}^{2-}$ to be around $0\,022 \pm 0\,004$, depending on the chlorinity, in reasonably good agreement with Garrels and Thompson[9] The very low activity coefficient of $CO_3{}^{2-}$ ion reflects the fact that most of the carbonate ion in seawater is complexed with various cations Using K_{sp} values from Latimer[10] and Jamieson[11] (K_{sp} at 25° C = $10^{-8\,24}$ for calcite, $10^{-8\,15}$ for aragonite), Berner calculated the degree of supersaturation for a typical warm (25° C) surface seawater to be 2 8 for calcite and 1 8 for aragonite On the other hand Li *et al*[6] conclude on the basis of their measurements and MacIntyre's values of K_{sp}' that the degree of supersaturation of calcite and aragonite in seawater is about 5 5 for calcite and 3 5 for aragonite There is no question that surface seawater is supersaturated with respect to both minerals at the present time, but there is some uncertainty as to the degree (4) The solubility of CO_2 and $CaCO_3$ (both aragonite and calcite) in seawater increase with decrease of temperature Therefore one needs to be concerned not only with what may happen in warm, tropical seas (at about 25° C) but also the subtropical ocean which Whitfield did not consider At mid to high latitudes the average sea temperatures are much lower and these areas would be the first to achieve undersaturation of aragonite with increase of P_{CO_2} Fortunately, the majority of calcareous organisms which flourish in the cold, subtropical seas are calcitic, and therefore less soluble, but aragonitic forms do occur[12] We have

observed (our unpublished observations) that surface seawater equilibrated at 10 °C with CO_2 at $P_{CO_2} = 1,000$ p p m is unsaturated with respect to aragonite, aragonite dissolves under those conditions One may therefore ask whether an atmospheric concentration of CO_2 three times the present value is likely to result from future fossil CO_2 production Zimen and Altenhein[4] estimated that P_{CO_2} values of 1,000 p p m will occur by about the middle of the next century We believe an atmospheric level of 1,000 p p m will occur sooner as Zimen and Altenhein's estimate is based on a box model in which CO_2 uptake by the sea is not restricted by the chemistry Our experiments show that ΣCO_2 of seawater increases much more slowly than the box model allows and thus the sea will not absorb as much CO_2 as Zimen and Altenhein calculated Consequently, P_{CO_2} will increase faster than predicted by their model The ocean's ability to absorb the anticipated future fossil CO_2 emissions is so limited that it is not so much a question of whether a level of 1,000 p p m can be reached as to when it will be reached (6) Elsewhere, Whitfield[13] re-examined the problem of $CaCO_3$ unsaturation as a function of P_{CO_2} and temperature He concluded that aragonite unsaturation can be expected to occur in subtropical seas (average temperature about 10 °C) before the middle of the next century His theoretical result is in good agreement with our experimental observations We conclude therefore that there are grounds for serious concern about the impact of fossil CO_2 emissions of the ocean.

Dr Whitfield replies — Fairhall and Erickson[1] have objected to several facets of a recent paper[2] in which I presented the chemical consequences of certain models[3-6] which have been used to pre-

dict the rate of fossil CO_2 accumulation in the oceanic mixed layer They emphasise[1], as I have done elsewhere[7,8], that the calculations[2] at 25 °C result in an increase in the carbonate alkalinity (CA) ($CA = [HCO_3^-]+2[CO_3^{2-}]$) which, as they conclude, indicates "that the increase in total CO_2 predicted by the mixing models (refs 3–6) is incompatible with the chemistry" The calculations[2,8] indeed provide strong grounds for rejecting the mixing models of Fairhall[5,6] and of Zimen and Altenhein[3,4] which predict gross accumulations of fossil CO_2 in the oceanic mixed layer I am glad that there is now some agreement on this point

The high value of ΣCO_2 that I used does not materially affect my conclusions Analyses of seawater from Plymouth Sound, using the titrimetric procedure described by Edmond[9], gave ΣCO_2 values that are comparable with those reported[1] (Table 1) The lower ΣCO_2 values, however, do not necessarily imply lower values of $[CO_3^{2-}]$ The carbonate alkalinity is a much better diagnostic criterion than ΣCO_2 as it also incorporates the effects of pH on the CO_2 system[7] It is possible to calculate the partial pressure of carbon dioxide required to reduce these samples to saturation level with respect to calcite or aragonite and also the pH at saturation level using the procedures described earlier (ref 2, equations (4), (6) and (7) and ref 7, equation (6)) MacIntyre's original value[10] ($10^{-6\ 26}$) was used for the solubility product of calcite at 25 °C and $35^0/_{00}$ salinity rather than the higher value ($10^{-6\ 17}$) quoted by Fairhall and Erickson[1] Similar values

have resulted from the recalculations of MacIntyre's data by Ben-Yaakov and Goldhaber[11] ($10^{-6\ 28}$) and by Ingle *et al*[12] ($10^{-6\ 30}$) The value quoted by Fairhall and Erickson[1] for the solubility product of aragonite is correspondingly higher than the original value

For Plymouth Sound samples at 25 °C, P_{CO_2} values seven to thirteen times those observed at present would be required for the mixed layer to approach the saturation level for calcite, depending on the solubility estimates used (Table 1)

These values are in excess of the most pessimistic predictions made so far for the accumulation of fossil CO_2 in the atmosphere[3,4] In some instances the calculated P_{CO_2} values approach the threshold limit value of toxicity (5×10^{-3} atm) They certainly identify as unrealistic those calculations[3,5] indicating that calcite saturation may be approached at 25° C following only a 50% increase in the current P_{CO_2} level The P_{CO_2} values for aragonite saturation at 25 °C are between five and eight times the present value These facts support my original conclusion[2] that, at 25 °C, "no account need be taken of the calcium carbonate equilibria since the mixed layer is supersaturated throughout and is likely to remain so" The editorial remarks appended to my original paper[2] which suggested that "serious environmental effects are not likely in the foreseeable future", do not, however, reflect my own conclusions

Preliminary experimental[1] (Table 1) and theoretical[7] results suggest that temperate waters (10 °C) may approach

Atmospheric halocarbons and stratospheric ozone

LOVELOCK[1] reports atmospheric analysis data for the fluorochlorocarbons (FCCs) CCl_2F_2 and CCl_3F in addition to the chlorocarbons (CCs) CCl_4, $CHCl_3$, CH_3Cl_3, $CHClCCl_2$, and CCl_2CCl_2 The synthetic FCCs are presently of concern as possible catalysts for the destruction of stratospheric ozone Although Lovelock states that "Molina and Rowland[2] rightly warn of a potential hazard to stratospheric ozone should the emission of the FCCs continue to grow unchecked", the levels of the CCs reported led him to conclude that "unless there is some special additional effect from the release of chlorine at higher altitudes, there are no grounds for singling out the FCCs as more hazardous than the other halocarbons which penetrate the tropopause"

I do not disagree with that as a statement of the present state of affairs, but I suggest that the conclusion, as stated, is likely to cause confusion as it does not distinguish between the present condition and the probable future values of the CC/CC ratio, the issue of central concern The following points seem to have been made by Lovelock or might be reasonably concluded from information presented by him (1) Present halocarbon levels are at the edge of significant participation in stratospheric ozone destruction cycles (2) CCl_4 and other CCs are present in far larger amounts than can be explained by reasonable estimates of synthetic sources, the present concentrations of CCs then represent essentially natural levels and are therefore not likely to change significantly in time

(3) The FCC analysis data suggest, however, that most of the FCC production to date is still present in the troposphere and lower stratosphere So the sinks for the naturally-occurring CCs do not seem to be significant for the FCCs For example, use of Lovelock's mole fraction of $1·0 \times 10^{-10}$ for CCl_2F_2 and an atmospheric scale height of 7 3 km lead to a value of $1·3 \times 10^9$ kg for the amount of this compound in a shell 10 km thick around the Earth This estimate is based on a low value for the tropospheric volume, neglects stratospheric content, and uses an analysis significantly lower than reported elsewhere[3] Use of a recent production rate of $0·5 \times 10^9$ kg yr^{-1} and exponential growth with a 3 5-yr doubling period observed back to 1960 (ref 4) gives an estimate of $2·5 \times 10^9$ kg for industrial production to date Thus a large fraction of the FCCs ever produced can still be accounted for in the atmosphere The only significant loss process would then seem to be diffusion past the tropopause and subsequent photolysis in the middle stratosphere

I conclude that the problem is not the consideration that the FCCs might have some special stratospheric reactivity in contrast to the effects of the CCs, as suggested by Lovelock, but rather that the FCC concentrations are likely to continue to grow to critical levels This has been illustrated by the model calculations of Cicerone, et al[4] Thus the FCC/CC ratio in the troposphere is most likely to increase steadily with time to a value significantly greater than unity with resulting future consequences for the ozone levels

Matters arising

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in *Nature* The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted Neither contribution nor reply (if one is necessary) should be longer than 300 words and the briefest of replies, to the effect that a point is taken, should be considered

PROFESSOR LOVELOCK REPLIES—If the models of stratospheric ozone destruction by odd chlorine are assumed, then I agree with Chesick that the uninterrupted exponential growth of FCC emissions must eventually establish an atmospheric concentration hazardous on a global scale In this limited context the only point at issue is when this concentration will be reached The atmospheric significance of a compound depends on the rate at which it releases chlorine in the stratosphere and this is a function of residence time as well as of abundance The FCCs have residence times of more than 50 yr whereas the CCs other than CCl_4, have residence times of less than one year A large fraction of the FCCs entering the stratosphere are returned to the troposphere unchanged, but most of the CCs entering the stratosphere are destroyed there

I suggested that there might be a large natural chlorocarbon cycle[1] Evidence gathered during the past six months considerably strengthens this conclusion R A Rasmussen (personal communication) has found substantial concentrations of methyl chloride in rural air on the West Coast of the USA I have confirmed this finding for air coming from the Atlantic with concentrations of methyl chloride now exceeding 10^{-9} by volume As our investigations proceed, the sum total of atmospheric chlorine carriers discovered grows much more rapidly than does the release of FCCs The measured ratio of CC to FCC chlorine is now approaching four

The models of ozone destruction by odd chlorine are plausible and do give cause for concern but in the debate it tends to be forgotten that the models are entirely unconfirmed by direct observations in the stratosphere

When all these factors are taken into account it does seem that there is time to make those stratospheric measurements from which a realistic upper limit to the concentration of anthropogenic chlorine compounds can be decided Tropospheric measurements are also needed to complete our understanding of the natural chlorine cycle

Alteration of chicken melanocytes by DNA

LANZA has reported that injection of Harco chicken DNA into 5-d-old White Plymouth Rock embryos permits production of melanin beyond day 14 of incubation, in contrast to uninjected embryos[1] He cites Hamilton's work, in which melanocytes were observed in embryos of all fowl examined, including breeds with white plumage, the melanocytes of white breeds were initially capable of melanin synthesis but degenerated

before hatching[2] Thus, Lanza states that DNA treatment extends the life span of such melanocytes Because of related studies in my laboratory, I would like to offer two possible interpretations of Lanza's observations

We have reported that injection of chicken DNA into White Leghorn eggs induces two types of effects on the embryos, depending on incubation conditions a lethal effect which may be mediated by a genetic-like mechanism and a survival-enhancing effect involving a non-genetic mechanism[3] Both effects are inducible by isologous DNA Highly polymerised DNA can also enhance mammalian cell viability *in vitro* under conditions excluding a genetic-like mechanism[4] Such a phenomenon might account for the extended survival of melanocytes in Lanza's system While we did not observe induction of pigment in more than 200 hatched chickens whose eggs had been injected with non-degraded DNA (either isologous or Rhode Island Red), our experimental procedures differed extensively from Lanza's

Second, several groups, including ours, have reported induction of melanin in mammalian cells by exogenous DNA[5-7] Detailed analysis of our data indicated that our effect was the result of alteration of a regulatory gene instead of a structural gene[8 9] This would seem to be the case for Lanza's system if it involved genetic transformation for pigmentation (instead of survival) As noted above, his target cells presumably contained genetic information for melanin production before DNA treatment

J LESLIE GLICK

Associated Biomedic Systems, Inc ,
872 Main Street,
Buffalo, New York 14202

DR LANZA REPLIES—The points made by Dr Glick are well taken A survival-enhancing effect similar to that cited[3], could indeed have extended the life span of the melanocytes reported

I would like to point out that all five of the embryos which had patches of pigmented feathers were examined between days 14 and 16 of incubation Although one of the newborn chicks developed some pigmented feathers, no pigment was observed in the juvenile down of any chickens hatched in earlier experiments This suggests that all the melanocytes were not altered permanently, and those that were, were too few in most cases to synthesise enough melanin to be detected in the juvenile down of a newborn chicken

Glick's experimental procedures differ extensively from the experiment reported Alterations in the embryonic stage would have gone undetected because he observed only hatched chickens It should be emphasised that the pigmentary genes in the White Leghorns referred to in Glick's response are considered dominant, whereas those in White Plymouth Rocks are considered recessive[10] I am led to conclude that any genetic transformation would be non-pigmentary and would directly involve the genes responsible for the degeneration of the melanocytes

Although Glick's analysis of induced melanin synthesis in mammalian cells indicated that the effect was due to a regulatory gene instead of a structural gene[8], he should not preclude the possibility of a structural gene defect in White Plymouth Rock melanocytes The lack of pigmentation in most mammalian cells results from a gene–enzyme defect, in which tyrosinase fails to catalyse the reaction in which tyrosine is hydroxylated to dihydroxyphenylalanine This is not the case, however, with White Plymouth Rocks as Glick stated, the melanocytes in that system were initially capable of melanin synthesis Therefore genetic transformations involving pigmentation in this breed, would not necessarily be the result of a regulatory gene

Schwarzschild orbital topography and high Doppler blueshifts

CHITRE, NARLIKAR AND KAPOOR[1] discuss the high Doppler blueshift of forward light emission from material particles in circular orbit in a Schwarzschild field at and near $r = 3GM/c^2$, which they claim is the radius of the unstable circular orbit (meaning, apparently, "the marginally stable circular orbit")

This supposed effect rests on a basic confusion concerning the orbital topography and energetics in the Schwarzschild field Outside the event horizon, at $r = 2GM/c^2$, there are three important circular orbits[2] the marginally stable circular orbit at $r_{ms} = 6GM/c^2$, inside which there can be no stable circular orbits (Chitre *et al*[1] mistakenly put this at $r = 3GM/c^2$), the marginally bound circular orbit at $r_{mb} = 4GM/c^2$, inside which there can be no bound circular orbits, and the photon orbit at $r_{ph} = 3GM/c^2$, which has an infinite energy

per unit mass and requires a tangential velocity $v_{tang} = c$ Chitre *et al*[1] seem to have confused the marginally stable circular orbit with the photon orbit So it is not surprising that they obtain an infinite blueshift there, since any particle in such an orbit must have $v_{tang} = c$ But, of course, massive particles are barred from such orbits, and those in circular orbits of radii approaching $r = 3GM/c^2$ are not only in an unstable configuration but also highly unbound ($E \gg 1 mc^2$) In any realistic physical situation they will all move along outward spiral orbits

Near $r_{ms} = 6GM/c^2$ particles will make many revolutions, but there will be no net Doppler blueshift, since for these $v_{tang} \simeq c/2$ As particles reach $r = r_m$ through, for example, viscous drift, the plunge towards the black hole along spiral orbits For a test particle moving along such a spiral geodesic, conserving total energy ($E_{ms} = 0 943\ mc^2$) a angular momentum ($L_{ms} = 3 46GMm/$ where m is the mass of the test particle 4 85 revolutions will be executed between $r = r_{ms}$ and $r = 2GM/c^2$ (W R unpublished), and the first four revolutions will be between $r = r_{ms}$ a $r = 5GM/c^2$ If dissipative and radiative processes are important, the spiral orbit will have even fewer revolutions S there seems to be little reason to expect that there could be a thin disk of massive particles executing even approximate circular orbits in the "high blueshi region" near $r = 3GM/c^2$

DRS CHITRE, NARLIKAR AND KAPOO REPLY—We meant what we said in ou paper The orbit in question is close t $r = 3GM/c^2$ as stated, and is not nea to $r = 6GM/c^2$ as Stoeger would have u suppose We are aware that these orbit are unstable and it is not intended tha the particle should circulate in suc orbits for ever The circular orbit meant to be an approximation to th geodesic trajectory of the infalling pa ticle with high energy and small impac parameter, as discussed by Misner *et al* Those authors have discussed gravitation synchrotron radiation from particle transiting close to $r = 3GM/c^2$ The and related references have already bee cited in our paper so no further clari cation is necessary

The reward system needs overhauling

IN this last week, and in this International Women's Year, the Royal Society marked the occasion by electing a woman as one of the thirty-two new fellows, and Fred Hoyle put the cat among the pigeons in Nobel wonderland by saying that Jocelyn Bell (now Jocelyn Burnell) ought to have got the prize for the discovery of pulsars One can always rely on the reward system in science to breed controversy

On the making of Fellows of the Royal Society there is, of course, no end of folk-lore, gossip and scandal This has been true since at least the eighteenth century, when membership of the society was a fashionable thing for London gentlemen As late as 1830 Charles Babbage could write "several times, whilst I have been consulting books or papers at Somerset House, persons have called to ask the Assistant-secretary the mode of becoming a member of the Royal Society I should conjecture, from some of these applications, that it is not very unusual for gentlemen in the country to order their agents in London to take measures for putting them up at the Royal Society" Now the society is so purged of its non-scientific attachments that it can reasonably be accused of being too addicted to the rewarding of those who practise science and too little aware of those who teach, communicate, document, administrate and philosophise about science It is somewhat silly that a first-class administrator with major achievements in advancing the organisation of British science should have to be admitted this year on the basis of being distinguished for scientific work which he had to give up ten years ago

It would be invidious to name individuals whose distinction will never be rewarded under the present state of affairs (*Nature* keeps a list of fifteen or so) But it should be pointed out that the mechanism for recognising "conspicuous service to the cause of science" exists but is restricted to one extra fellow a year—at present only eleven fellows are in on that ticket, including two royals and five politicians The mechanism also exists for "general candidates" to be admitted, although the committee charged with presenting names does not seem to have outstanding success in leavening the fellowship By all accounts the process of selecting fellows is a parochial affair in which no external advice is sought, this may assure main-line excellence, but it doesn't recognise the new dimensions of science which represent its internal and external interactions

In the past 30 years the representation of women in the society has actually declined Of those present fellows, seven were elected between 1946 and 1955, eight between 1956 and 1965 and eight in the past 10 years In the same period the total number of new fellows elected has risen from 25 to 32 annually The society can hardly be blamed for the shortcomings of a system in which it is still difficult for women in large numbers to pursue science with anything approaching the single-mindedness that intellectual distinction demands On the other hand women, with every justification, are looking for some redressing of the balance This has called in some countries for positive action by institutions, and it would be good to see the Royal Society give a lead in asking the question—how can we recognise the contribution that women make to science? More than 10% of the authors of papers in this journal are women and most of our authors are relatively young, yet by the time that they have reached an age at which they are recognised as distinguished, the proportion has dropped to about 3%

Finally, astronomy has now had the Nobel plague descend on it The joy of astronomers that at long last a Nobel prize is within their grasp is likely to be shortlived when they discover how divisive the whole concept of vast cash awards and hob-nobbing with royalty is to the scientific community Fred Hoyle's complaint, however justified or unjustified, is only an early shot in a battle which will set scientists against each other in years to come as more astronomers get rewarded, and others go unrewarded

The trouble with Nobel prizes is threefold First, there are clearly not enough to go around, and hence there is bound to be inequity in their distribution Second, they tend to be confined to a restricted number of subjects, giving a false impression of the relative importance of various fields Third, they confer an unreasonable amount of credit on their recipients leading to Merton's well-documented Matthew effect ('to him that hath, it shall be given') and often to the less well-documented Boeing complex ('given the option between jetting around the world lecturing on things you don't know much about and staying at home working, go for the jet-trip any day')

In certain subjects and certain laboratories one gets the distinct impression that the pursuit of Nobel prizes is the ultimate aim, rarely spoken of but rarely very far below the surface Ambition is a fine thing but these inequitable, divisive, flattering prizes generate obsession Isn't it time they were abolished? □

Plutonium particles: some like them hot

The Medical Research Council's 1975 report The Toxicity of Plutonium (Nature, 253, 385) concludes that "there is no evidence that irradiation by 'hot particles' in the lung is markedly more hazardous than the same activity uniformly distributed or that the currently recommended standards for inhalation of plutonium are seriously in error" Report R29 (1974) of the National Radiological Protection Board (NRPB) states that "there is no biological evidence available at present which suggests that 'hot spots' carry a higher risk of cancer induction" But in the March 20, 1975 New Scientist, Dr A R Tamplin warns "The plutonium exposure standards must and will eventually be made more restrictive by a factor approaching 1,000" Behind this disagreement is a major controversy over the risk of lung cancer from inhaled insoluble particles of intensely radioactive alpha emitters such as plutonium In that controversy—unresolved by any direct data—lies a source of uncertainty about the future of nuclear power A report by Amory B Lovins and Walter C Patterson of Friends of the Earth

SINCE the late 1960s, many experts— Geesaman, Langham, Long, Morgan among others—have expressed concern about the formidable but highly uncertain toxicity of plutonium (Pu) aerosols On February 14, 1974, Drs Tamplin and Cochran of the Natural Resources Defense Council (NRDC) took action They petitioned the United States authorities to reduce the maximum permissible lung burden (MPLB) and maximum permissible concentration in air (MPC$_a$) of insoluble Pu by 115,000 times Also in 1974, the US Atomic Energy Commission published two defences of present standards, LA-5482-PR and WASH-1320, and in May and November NRDC published interstitial rebuttals to which the AEC declined to respond in writing or otherwise The NRDC petition is under review by many US official bodies, and the AEC's successor agency should announce its next move in April

The cancer risk from microscopic inhaled particles of insoluble Pu and similar actinides arises because such particles can deposit in deep lung tissue, can stay there for a year or more, and, being hard alpha emitters, can irradiate only that tissue which is within ~ 40–45 µm This last property makes it hard to determine the MPLB and MPC$_a$, for these are derived from an international standard which says merely that lungs should not be exposed to more than 15 rem of radiation per year Fifteen rem is equivalent to 1 5 rad of alpha radiation (since alpha radiation is considered 10 times as carcinogenic as gamma radiation), and a rad, the basic unit of "radiation absorbed dose", is that amount of radiation which deposits 100 erg of energy per gram of tissue irradiated But which tissue is that? Present practice is to average the alpha dose over the entire 1000-g pair of lungs whether it all receives alpha radiation or not

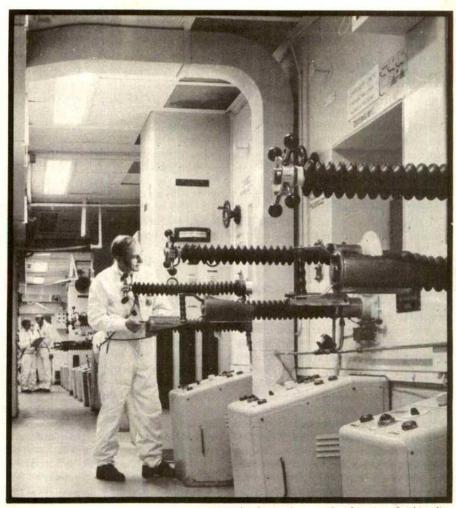
This practice is illustrated in Table 1, which shows approximate data for some hypothetical distributions of one MPLB of the dominant isotope ^{239}Pu (16 nCi = 0 016 microcurie, the amount whose

annual radiation dose, averaged over 1,000 g of lung tissue, would be 15 rem) For convenience, and with no pretence at realism, Table 1 assumes that this MPLB is uniformly distributed in the lungs with varying degrees of aggregation, ranging from a single 37-µm particle (actually too big to be respirable) to ~ 50 million 0 1-µm particles But each ^{239}PuO$_2$ particle, however large, can only irradiate ~ 50–100 of the several hundred million alveoli, therefore an MPLB uniformly distributed as particles larger than ~ 0 15 µm must irradiate some lung tissue at more than 15 rem per year and some other tissue not at all (Non-uniformly distributed particles, as they would be in reality, would give non-uniform doses at even smaller particle sizes) Nonetheless, the mean lung dose, now used to set the MPLB and MPC$_a$, would be 15 rem per year in each case shown, and each would be assumed to carry the same cancer risk

The issue posed by Table 1 is whether intense irradiation of a very small mass of tissue is more carcinogenic than less intense irradiation of a proportionately larger mass, that is, if a given amount of intense irradiation is distributed more evenly over lung tissue, whether the greater number of cells at risk exactly compensates for the smaller risk per cell An hypothesis that this were untrue would imply that carcinogenesis is not linearly proportional to dose at very high dose levels because intense local irradiation can bring to the fore some new mechanism(s) absent or unimportant at lower doses (Loosely speaking, this is a "threshold" theory, but one applying to high doses, not low ones people who argue for non-linearity in the low-level radiation controversy tend to argue against it in the hot-particle controversy)

Such a high-dose mechanism might involve (for example) carcinogenic or contributory chemical activity by fragments of killed, fibrotic, liquefied, or otherwise seriously disrupted cells, rather than (or in addition to) "primary" or direct carcinogenesis by disruption of, say, a chromosome Such a "secondary" mechanism may coexist with other mechanisms, is plausible, and has respected adherents, but has not been directly demonstrated Neither, however, has any other proposed mechanism of radiation carcinogenesis, primary or secondary

The International Commission on Radiological Protection (ICRP) have sometimes had to introduce a Distribution Factor into the rad-to-rem conversion to allow for inhomogeneous doses within a "critical organ" Thus the dose limit for bone is based on uniformly deposited ^{226}Ra, but Pu, collecting at the bone surface, is considered ~ 5 times as radiotoxic, so a Distribution Factor of 5 is used to compute Pu bone dose Likewise, IAEA TR-142 (1973) reports

Table 1 Some illustrative and hypothetical uniform distributions of 16 nCi (= 1 MPLB) of ^{239}PuO$_2$ in 1 kg of lung tissue


Number of particles	1	50	5×10^4	$1 5 \times 10^7$	5×10^7
Particle diameter (µm)	37	10	1	0 15	0 1
Particle mass (ng)	300	6	0 006	2×10^{-5}	6×10^{-6}
Particle activity (pCi)	16,000	300	0 3	0 001	3×10^{-4}
Notional lung mass irradiated	65 µg	3 3 mg	3 3 g	1 kg	1 kg
Fraction of 1 kg	7×10^{-8}	$3 3 \times 10^{-6}$	0 0033	1 0	1 0
Local tissue dose	200 Mrem/yr	4 Mrem/yr	4 krem/yr	15 rem/yr	15 rem/yr
Mean dose to 1 kg lung tissue	15 rem/yr	15 rem/yr	15 rem/yr	15 rem/yr	15 rem/yr

The distributions shown in the last two columns give a local-tissue dose equal to the average lung dose because the radiation fields of that many particles must overlap, whereas in the first three columns, the radiation fields from so few uniformly distributed particles are insufficient to "fill" the lung In reality, the distribution would not be uniform, and the latter position would arise with particles smaller than shown in the last two columns Two further points about half the energy of the alpha radiation is dissipated in the first 20 µm of tissue radius, or in about 1/8 of the volume irradiated by each particle, and since some attenuation of the alpha radiation in a spongy lung occurs in air rather than in tissue, the mass of tissue irradiated by each particle, and hence the reciprocal of dose to that mass, would be less in compact soft tissue such as skin

that "because it had been recognised that the dose distribution [from inhaled radon daughters] in the respiratory tract was inhomogeneous and the maximum alpha dose was delivered to the bronchial epithelium" rather than to the whole lung, the ICRP suggested a Distribution Factor of 10, owing to evidence that uranium miners were getting lung cancer more often than the average-lung-dose model had predicted. So far, no Distribution Factor > 1 has been applied to Pu in lung; and NRDC suggest, in effect, that the "critical organ" limited to 15 rem per year should be not the complete pair of lungs, but rather the tissue irradiated within it. Otherwise, using the dose-averaging concept, a Pu particle in beagle lung would be 8 times as carcinogenic as the same particle in human lung (neglecting species differences) simply because human lung is 8 times as large. Indeed, if each of two men had an identical Pu particle in his left lung but the right lung of one man had previously been removed, his computed risk of lung cancer from the particle would be twice that of the other man! This *reductio ad absurdum* shows the artificiality of averaging very localised doses over entire organs.

The ICRP have explicitly declined to offer guidance in this area: as the NRPB state, "radiological protection standards cannot be applied to small volumes as they have been derived from observation of biological effects in the whole body or in body organs." Experiments have shown, however, that intense irradiation of, or other insults to, small amounts of various tissues (including bronchial and lung tissue) can produce tumours or other lesions showing cellular changes characteristic of precancerous lesions. Indeed, Pu particles in rat lung have been shown to cause lesions similar to one observed around a 5-nCi [239]Pu particle excised in 1962 from a worker's palm: this lesion showed "severe" changes similar "to known precancerous epidermal cytological changes". There is strong evidence, too, associating a fatal soft-tissue sarcoma in a US worker with entry, through some minute cut, of Pu solution that had spilled on his hand. Thus cancer, or lesions suggestive of eventual cancer, is demonstrably induced in both man and laboratory animals by very intense irradiation of very small amounts of various tissues, including rat lung. But does the incidence of such effects exceed that observed for lower intensities applied to proportionately larger amounts of tissue?

No direct answer is available for inhaled insoluble Pu. Disquieting long-term experiments with beagles have shown that almost 100% of dogs inhaling Pu doses down to 200 nCi ($\sim 10^7$ particles) get lung cancer within $\sim$ 11 years, but experiments with lower doses will not yield data for many years. The evidence

Windscale: workers on the plutonium finishing line

must therefore be indirect, so one must decide what evidence is relevant and hence exactly what is a "hot particle". The February 1974 NRDC definition, based largely on work by Geesaman, is an alpha–emitting "particle in the deep respiratory tissue of such activity as to expose the surrounding lung tissue to a dose of *at least* 1,000 rem in 1 year." New data (including human autopsy data) discussed by NRDC in a February 1975 paper suggest that a lower limit for hot-particle activity might be anywhere from 0.07 pCi (derived from the 1 krem per year criterion) to perhaps 4.2 pCi, —a four-fold range of particle diameter— depending on the data and degree of conservatism chosen. NRDC also prefer to define the limit not by calculated local dose but by particle activity, which can be correlated with observable phenomena: some levels of activity produce fibrotic lesions whilst others do not.

Clearly it is necessary to assume some lower activity limit distinguishing the hot-particle carcinogenic mechanism from that of uniform dose, and any such postulated limit must have a certain arbitrariness which invites challenge. (The limit may not in reality be so clearly defined.) Suggestively, the 0.07-pCi limiting activity originally proposed by NRDC is substantially above the level at which

uniformly distributed particles totalling 1 MPLB cannot irradiate the whole lung (Table 1).

No quibbling can arise over whether a particle is a hot particle if its activity is orders of magnitude too low to cause observable discrete lesions. The particles used in many experiments, those produced by fallout from nuclear testing, and those inhaled by the often-cited 25 Manhattan Project workers are all in this category and hence cannot be used to test the NRDC hypothesis. At least 25 other workers did inhale hot particles from the 1965 Rocky Flats fire, and linear extrapolation from the beagle data suggests that these men are likely to develop lung cancer after an unknown induction period, probably of several decades.

Many critics of the hot-particle hypothesis do not state whether the experiments they cite involve hot particles. For example, the NRPB's dismissive review of the NRDC hypothesis relies heavily on an unpublished paper of Lafuma, comparing the incidence of lung cancer in rats after inhalation of "particulate" [239]Pu or "diffuse" [242]Cm. NRPB claim a lower incidence for the former doses, but give no data, and one is entitled to wonder whether the [239]Pu was in the form of hot particles, what the doses were, whether the lifespan of the rats exceeded the

induction time of the effects sought, what allowance was made for the 23-week half-life of ^{242}Cm and so on. Inquiries to NRPB in January, 1975 elicited the astonishing reply that such basic data as particle size and activity were not in Lafuma's paper and must be sought from him. (An immediate letter to that end has had no reply at this writing.) So it is not clear whether the NRPB's crucial experiments involve hot particles at all.

Even if they do, the data are still consistent with the hot-particle hypothesis. Experiments suggesting that tumour incidence per nCi is greater with uniform than with discrete dose distribution—or the opposite, as both can be shown—are not relevant to, nor a test of, the hot-particle hypothesis: the latter bears on the risk per hot particle, not the risk per nCi. If the hypothesis is right, then increasing the activity of a hot particle—one that is already large enough to bring into play the postulated high-dose mechanism of carcinogenesis—only further disrupts already-killed cells and does not significantly increase the risk from that particle, though it reduces the apparent risk per nCi. Thus the hypothesis already contains the concept of "overkill" or "wasted radiation". Table 2 shows six hypothetical experiments devised by NRDC: *A-D* suggest that discrete dose is less hazardous than uniform dose, *E-F* suggest the opposite, and *A-F* are all consistent with the hot-particle hypothesis.

The NRDC rebuttal of WASH-1320 appears to show that all experiments there cited are either irrelevant to the hot-particle hypothesis or consistent with it. The irrelevance arises because for example, experiments do not involve insoluble hot particles in lung, or use short-half-life actinides, or show rapid lung clearance, or have been interpreted on a risk per nCi basis, or use animals that do not survive the induction period, or do not wait for it to elapse, or mask the lung-cancer response with other pathological conditions, or do not involve significant samples.

The MRC report, apparently initiated by the NRDC petition, cites it as the work of "an organisation called the Environmental Defense Research Council concerned with problems of pollution in general" (wrong on both counts) and, like the NRPB report, ignores the two 1974 NRDC rebuttals which follow up the original petition and anticipate the MRC and NRPB arguments. (The MRC report does not even cite the two AEC responses to the NRDC petition.) By failing to read these papers or to contact NRDC, the MRC and NRPB have lost an opportunity to raise arguments not already canvassed. They have stressed the quantitative uncertainties (limiting particle activity and risk per particle) but have not disproved the basic thesis. Instead, they prefer to argue that "there is no evidence" for the NRDC hypothesis—

whilst ignoring much of the evidence NRDC cite in their original paper, notably reports of Pu-induced lesions in both rats and man. But the "no evidence" argument cuts both ways. There has been no concerted effort in Britain to imitate the new US Transuranium Registry of radiation workers, which it is hoped will eventually find the epidemiological evidence if it exists. To argue from the general absence of evidence (for which one has not looked) that there is no evidence for one's opponent's point of view is to write with an economy of truth.

The main drawback of the hot-particle hypothesis seems to be that it requires one to assume an unproven and somewhat vague cellular mechanism of radiation carcinogenesis operating at high dose levels. Yet critics of the hypothesis have been unable to demonstrate any mechanism underlying their own theories, and until they have done so, it is hard to see how other mechanisms can be definitely excluded. The resulting scientific uncertainty, and its likely persistence, raise an important ethical and political issue. We have an hypothesis, neither proved nor disproved, implying that the MPLB and MPC$_a$ for insoluble aerosols of Pu and similar actinides—inherent in a large-scale fission economy—should be reduced by orders of magnitude. We have two choices: (1) ignore the hypothesis as unproven, continue our research, continue to expose some radiation workers to hot particles, assume that these are innocuous, and proceed to make the world's energy supplies dependent on annual flows of hundreds of tons of Pu; or (2) provisionally adopt the hypothesis until it is disproven, tighten standards accordingly, and thus act with the caution, prudence, and conservatism which—we are told—are the basic principles of radiation protection. So far, regulatory bodies have taken the first course, gambling that exposed Pu workers will not begin, a decade or two hence, to show excess lung cancers as some analysts claim they are now beginning to show excess leukaemias.

The reason for this gamble may be related to a little-known fact: that even the present MPLB and MPC$_a$ for insoluble Pu are near the limits of practical detectability, not because we lack sensitive instruments but for fundamental statistical reasons. It is not clear that present monitoring methods at, say, Windscale can demonstrate compliance even with present standards: a "puff" release from,

say, a defective glove-box may be hidden in the 24-hour integration period of air samplers, and even a real-time radiation monitor could probably not detect significant Pu levels in a typical room before most of the air in it had been inhaled or changed. If the standards became much stricter, compliance could never be shown and the standards would have no operational meaning. Whether a Pu-fuelled industry could then operate would depend on whether the burden were on it to prove compliance (impossible) or on others to prove non-compliance (presumptive but debatable) and on how strictly the relevant duties were construed.

The questions of monitoring and enforcement are not academic; they are the crux of the matter, for a few decades from now the growing gap of magnitudes between world Pu stocks (thousands of tons) and the amount which can produce a nuclear explosion (a few kg) or give a beagle lung cancer (a few μg) will require impressively and increasingly diligent care to prevent releases through accident or malice. Pu metal, nitride and carbide can be pyrophoric, burning to respirable PuO$_2$; this insoluble ceramic is itself present in advanced nuclear fuel cycles, can pass in respirable sizes through high-efficiency filters, and has contaminated dozens of Pu workers in accidents here and abroad. Pu fires have released tens or hundreds of grams of PuO$_2$ from US facilities and far more within them. Pu could be released by fast-reactor accidents, weapons explosions, deliberate dispersal, or chemical or microbial action on Pu-bearing wastes (like the dilute alpha wastes buried at Drigg near Windscale). Biological pathways for reconcentration of Pu—now discharged in hundreds of Ci per year from Windscale into the Irish Sea—may exceed those now known, as Pu chemistry is very complex. Since the half-life of ^{239}Pu is 24,390 years, and since fallen-out aerosols may become resuspended (data on this vary over 11 orders of magnitude), dispersal may be essentially permanent. In an energy economy based on hundreds, then thousands, of fast breeder reactors, each containing several tons of Pu, even if Pu escape were controlled with the most exquisite care, the unavoidable limits of *in vivo* and environmental measurement would make it impossible to tell whether we were meeting stricter Pu standards or not. We could only tell from increased lung cancers—decades after the irrecoverable releases had occurred. ☐

Table 2 Some hypothetical hot-particle experiments

Experiment	A	B	C	D	E	F
Number of hot particles	6000	4000	2000	200	6000	4000
Total activity (nCi)	12	12	12	12	12	6
pCi/particle	2	3	6	60	2	1.5
Number of tumours observed	3	2	1	0	3	2
Tumours/nCi	0.25	0.17	0.08	0.00	0.25	0.33
Tumours/particle	0.0005	0.0005	0.0005	—	0.0005	0.0005

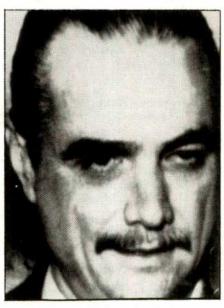
'Jennifer' subterfuge scuppered

by Colin Norman, Washington

Hughes: obsessively secretive

THE dramatic revelation that the Central Intelligence Agency (CIA) last year secretly salvaged part of a Soviet missile-carrying submarine from the bottom of the Pacific, could hold some important implications for oceanographic research. Though such concerns are dwarfed by the wider political ramifications of the affair, some knowledgeable observers last week pointed out that the CIA's salvage job could affect the outcome of the Law of the Sea Conference which is now grappling with, among other things, issues concerned with freedom to carry out research in, on and under the high seas. Moreover, the affair could upset the flourishing co-operation between the United States and the Soviet Union on oceanographic research.


The operation had all the essential ingredients of a James Bond thriller, involving as it did a national intelligence operation, an elusive billionaire, an elaborate cover, and hundreds of millions of dollars. For five years it was also one of the Nixon and Ford Administration's best kept secrets, until a number of newspapers last week decided to print the details, in spite of frantic attempts by the CIA to keep it bottled up.

Known as Project Jennifer, the operation began to take shape soon after the submarine sank in about 16,000 feet of water in 1968, about 750 miles north-west of Hawaii. Intelligence sources in the United States knew the exact location of the vessel because they were able to pick up underwater explosions from it, but Soviet ships looked for it in the wrong area according to a report in the *New York Times*. When the Soviet ships abandoned their search, the CIA decided to try a salvage job itself.

The cover for Project Jennifer was inspired, to say the least. A special salvage ship was constructed for the CIA by Summa Corporation—a huge industrial concern operated and owned by Howard Hughes, the eccentric and elusive billionaire—and it was publicly billed as being the biggest seabed mining vessel ever constructed. Another essential component of the operation, a massive submersible barge, was built by the Lockheed Coporation; it was also depicted as playing a central role in bringing manganese nodules to the surface, but its sole function was to hide the submarine when it was recovered.

Because the nascent technology of seabed mining was jealously guarded in the early 1970s by the few companies hoping to scoop manganese nodules from the ocean floor, and because Hughes has a reputation for obsessive secrecy, few questions were raised about the clandestine nature of the operation. Moreover, the submarine went down in an area of the Pacific where manganese nodules are known to litter the seabed.

The salvage ship, known as the Hughes Glomar Explorer, was launched in 1973, and it made its first salvage attempt in July and August last year. According to reports, it succeeded in lifting the submarine from the sea bed, but recovered only a part of it. Although some of the accounts are conflicting, it is widely believed that the CIA failed to retrieve the two chief items it wanted—the nuclear-tipped missiles and code machines — and another attempt was being planned for later this year. But publication of the details has, apparently, scuppered that plan.

As far as the implications for research are concerned, one important aspect of the affair is that the Glomar Explorer was operated by Global Marine Inc., a company which has built, owns and operates a number of oceanographic research vessels. Prominent among its fleet is the Glomar Challenger, the highly successful drilling vessel which is operated under contract to the National Science Foundation, and which has been conducting the six-year-old Deep Sea Drilling Project (DSDP).

Last year, the Soviet Union joined the DSDP, and it is now contributing $1 million a year to the project. Although the Soviet government had made no comment on the CIA's salvage job by the end of last week, one US official connected with the DSDP speculated privately that the Soviet Union may now reconsider its participation, in view of Global Marine's connection with the CIA.

Moreover, one newspaper account even suggested that the Glomar Challenger had played a direct role in the initial reconnaissance for Project Jennifer, but that report was hotly denied by the National Science Foundation (NSF). For one thing, as the vessel's publicly available logs show, it was not in the vicinity of the submarine at the time, and for another, two Soviet Academicians were aboard when it was alleged to be scouting out the wreck. An NSF spokesman also pointed out that the Glomar Challenger has been operated continuously under contract to the foundation since it was launched in 1968, and at no time could it have been diverted to the CIA's operation.

As for the Law of the Sea Conference, one issue to be resolved is the extent to which oceanographic research should be allowed to take place unhampered both on the high seas and also within the 200-mile 'economic zones' which may be established around the coasts of maritime states. The nub of the issue is that most industrialised nations are arguing for scientific research to be permitted unimpeded outside territorial waters. But the developing nations have generally argued that research operations could provide a cover for economic exploitation of seabed minerals, and for espionage. The CIA's cover for Project Jennifer provides all the justification in the world for such fears.

The point has not been lost on delegates attending the Law of the Sea

Conference which, ironically, reconvened last week in Geneva. According to another *New York Times* account, Christopher W. Pinto, a delegate from Sri Lanka and a leading spokesman for the developing nations, has already said that the CIA operation has undercut the argument for freedom for research. He is quoted as saying that the developing nations have been suspicious that research activities may provide a cover for other operations, and "now that this is confirmed, they [the developing countries] can be more forceful".

Another aspect of the salvage operation is important for the development of undersea technology: by depicting the Glomar Explorer as a deepsea mining vessel, the CIA provided the greatest possible incentive for other mining companies to step up their operations. When the ship was being built and operated, it was generally assumed that Hughes was leading the field in the race to scoop manganese nodules from the deep sea bed.

During Congressional hearings in 1973 and 1974, for example, representatives from other prospective seabed mining companies argued vigorously for Congress to pass legislation which would offer them some financial security so that they could raise and invest vast amounts of capital in the technology. Although Congress did not pass the legislation, there is little doubt that the prospect of Hughes beating the rest of the industry to the seabed riches stimulated frenzied efforts in other companies.

It is unclear, however, whether or not the Glomar Explorer could be used for seabed mining. It is also unclear who would own and operate it for such activities, although a good case could be made out for the argument that it belongs to the federal government.

As a footnote to the operation, it should be pointed out that Project Jennifer reportedly cost about $350 million, which is considerably more than the federal government's entire budget for oceanography for the past five years. The money was, however, provided with the knowledge of very few Members of Congress and of only a few people in the Administration. ☐

Call for cuts in astronomers

by Colin Norman, Washington

A COMMITTEE of the National Academy of Sciences this week made the painful and perhaps unprecedented recommendation that graduate departments in the United States should reduce their output of astronomers because of dismal employment prospects and sagging financial support for astronomy.

Although other groups of scientists have urged that production of PhDs in some fields should level off, few have openely called for graduate education to be cut back. But the situation in astronomy is considered so serious that "we can't just sit and wail about it", Dr Leo Goldberg, Director of the Kitt Peak Observatory and chairman of the Academy committee, said in an interview last week. He added that even if enrolment in PhD courses in astronomy and astrophysics were cut in half, there would still be too many astronomers chasing too few jobs.

The problem is familiar enough. Force-fed by direct government support and by the burgeoning space programme in the early 1960s, astronomy experienced a period of spectacular growth, and graduate departments expanded rapidly. But, just as large numbers of astronomers began to emerge from the universities with freshly minted PhDs in the late 1960s

and early 1970s, government support slackened and job opportunities rapidly dried up. And the situation is getting worse because, unlike most other fields of science, graduate enrolment in astronomy is continuing to increase so that the supply and demand for young astronomers is going to get further and further out of balance.

To put the matter in perspective, Goldberg suggested that employment is likely to be available for only about 50 new astronomers a year, but last year alone the universities awarded more than 180 PhDs in astronomy and astrophysics. Adding to the problem is the fact that many people with doctorates in other branches of physics will be chasing jobs in astronomy and moreover, there are now between 150 and 200 astronomers holding temporary postdoctoral appointments who have no prospects of moving on to full-time employment, Goldberg said.

The growth in university astronomy departments may reflect the fact that the science continues to be intellectually exciting. But these days, intellectual excitement does not guarantee government support, particularly when large capital expenditures are constantly required.

According to figures gathered by the committee, funding for astronomy peaked in 1968 at about $227 million, and by 1972 (the latest year for which figures were available) it had shrunk to $187 million. And there are scant prospects of significant growth in the next few years, particularly in space astronomy. Recently, for example, the space shuttle has been taking up a growing share of NASA's stagnant budget and there is every reason to expect the trend to continue.

In view of the prospects of expanding graduate enrolment in astronomy and shrinking financial support for the science, the committee has suggested a number of controversial remedies.

● Most important, the rate of production of astronomers should be reduced, and "it is the responsibility of every university department which produces PhDs with specialisations in astronomy and astrophysics to assist in achieving this reduction", the committee states. All PhD students should be informed of the employment situation before embarking on graduate work, they should be carefully screened during the early years of their studies and the weaker ones should be weeded out. Goldberg also suggested that a limit should be placed on the number of universities offering PhDs in astronomy and astrophysics, so that as new departments are set up, older and less productive ones are phased out.

● To make astronomers more employable in other fields, the committee recommends that PhD astronomy

BRITAIN's nuclear power industry has been further streamlined with the announcement last week of the merger of Britain's two nuclear power groupings, British Nuclear Design and Construction (BNDC) and the Nuclear Power Group (TNPG), into one company, the Nuclear Power Company (NPC), which has been acquired by the National Nuclear Corporation (NNC). The government has agreed to make an *ex gratia* payment of up to £1.416 million to the shareholders of the now defunct companies for "unrecovered expenditure". Announcing the payment, Secretary of State for Energy Mr Varley said that the acquisition of the two consortia with their staffs by the NNC was "an important step forward". The acquisition includes the govern-

ment's 26% stake in British Nuclear Design.

The shareholding structure of the NPC and the names of the chief executives will be announced in the next few weeks, and it is expected that GEC, who were in favour of building the light water reactors rejected by the government last year, will drop its shareholding to 30% from the present 50%, with the UK Atomic Energy Authority increasing its stake from 15% to 30%.

The two existing bases, at Risley, Cheshire, where the design for the steam generating heavy water reactor is being carried out and Whetstone, Leicestershire, where work on the last two advanced gas-cooled reactors is continuing, are being retained for the "foreseeable future".

REPORTS from Moscow indicate that a new campaign is in preparation against the illicit "Sunday seminars" of *refusnik* scientists. Since the departure for Israel of Professor Aleksandr Voronel, founder of the seminar, the group has continued to meet, the venue alternating between the apartments of three leading members: mathematician Aleksandr Lunts, and physicists Viktor Brailovskii and Mark Azbel.

Of these three, Lunts has been threatened by the KGB with a show trial under Article 64 of the Soviet Penal Code, which relates to treason, which could result in a death sentence. The charge, phrased in deliberately vague terms, being that he had "undertaken a task on behalf of someone outside the Soviet Union for monetary gain".

Brailovskii, while not directly threatened, was called in for a discussion with Investigator Aleksandrov, who informed him of the charges being prepared against two other dissidents, dentist Mark Nashpits and engineer Boris Tsitlionik.

Mark Azbel, so far, does not seem to have attracted the attention of the authorities to the same degree, although there has been the usual routine harassment, and being a theoretical physicist, he is making a determined effort to continue his academic work, although cut off from all libraries and other facilities. The events of the last few years, however—arrests, hunger-strike and the nervous stress caused by constant uncertainty—has resulted in considerable deterioration of his health (he is suffering from severe cholelithiasis with reflex attacks of angina pectoris), and any increased pressure from the authorities could have very serious consequences.

● A DECREE of the Central Committee of the Communist Party of the Soviet Union (CPSU), published on March 21, 1975, states that the Jubilee Meeting of the Academy of Sciences of the USSR will be held in October 1975.

This meeting, originally scheduled for May 1974, was postponed, ostensibly on the grounds that further preparatory work was needed, although, at the time, the decision to cancel the planned international gathering was widely assumed to be connected with the concern expressed by Western scientists about the lack of academic freedom in the USSR and, in particular, the plight of Soviet Jewish scientists wishing to emigrate to Israel. This assumption was reinforced by the notice of postponement, which suggested that the celebrations would now be aimed at the grass roots of Soviet society.

The text of the new decree, after commenting on the successful local celebrations held throughout the Soviet Union on the theme "The achievements of science are for the national economy", states that the Jubilee Session of the Academy will be held "in Moscow, in October this year, with the participation of a Party, Soviet and community organisations, representatives of workers, scientists from the Academies of Science of the [constituent] republics, the Academy of Medical Sciences of the USSR, the Lenin All-Union Academy of Agricultural Sciences and the Academy of Pedagogic Sciences of the USSR. The Academy of Sciences of the USSR is given the task, together with the Jubilee Committee, of working out and presenting to the Central Committee of the CPSU proposals connected with the accomplishment of the celebrations of the Jubilee of the Academy of Sciences of the USSR.

"The Central Committee of the CPSU expresses its assurance that the Jubilee Session of the Academy of Sciences of the USSR in honour of the 250th anniversary of its foundation will be interpreted as a nation-wide festival, and will be conducted under the badge of a review of the achievements of Soviet science and the mobilisation of scientific teams for the solution of the problems proposed by the Twenty-fourth Party Congress on the acceleration of the rates of scientific and technological progress, ensuring the economic might of our homeland, strengthening the defensive potential of the country, raising the material prosperity of the workers, consolidating peace, and strengthening friendship b e t w e e n nations."

courses should be broadened to include experience in teaching, computer applications and electronics. "It is up to the entire community of astronomers to correct the image that astronomers are able only to look through a telescope and ponder the riddles of the universe," the committee adds.

● To help create more jobs for astronomers, the committee recommends that undergraduate astronomy programmes should be expanded. At present, the bulk of the astronomy community is employed in departments which award PhDs, and very few are to be found in undergraduate departments and colleges; the expansion of undergraduate astronomy courses would therefore help open up teaching posts. Coupled with that suggestion, the committee recommends that astronomy centres should establish arrangements for carrying out collaborative projects with astronomers in more 'isolated' research environments—such as undergraduate departments and liberal arts colleges.

Although there is considerable financial incentive for universities to carry on expanding their postgraduate departments, Goldberg said he has "considerable optimism that the recommendations will be taken up" and he pointed out that Harvard has already cut enrolment in astronomy PhD courses. □

Sweden's nuclear power game

from Wendy Barnaby

SWEDEN's nuclear future has been decided—officially until 1985. The ruling Social Democrats' energy plan, put to Parliament last week and expected to be approved, provides for the construction of nine reactors. With the four already in operation, Sweden will have thirteen reactors with a total electrical generating capacity of about 9,500 MW by 1985. This will be only two more than previously planned, but the increase is seen by critics as the thin end whose wedge will be an existing government plan to build 24 reactors by 1990. Construction on that scale would make the Swedes the world's greatest per capita users of nuclear power.

The plan is a piece of politics worthy of Prime Minister Olof Palme's considerable skills. Forced last year by public concern over the nuclear programme to postpone a decision on those plants not then under construction, he has with the present proposal given the appearance of responsible caution while allowing his government a reconsideration in 1978 of the ways energy is to be provided for 1985–90. By 1978, he explained, there would be more knowledge available on which to make a better-informed decision. By 1978, he could have added, the next parliamentary election will be safely out of the way with the emotional energy issue securely pegged for future consideration.

On the face of it, nuclear power seems an obvious choice for Sweden. Although the country has no cheap uranium resources (that is, uranium which can be mined for less than $10 a pound), it has almost half the non-communist world's known supplies of uranium in the next price range—$10–15 a pound. It has been estimated that the supplies of cheap uranium may become scarce in the mid-1980s, partly because of the eight-year time lapse between discovery and production of deposits. Unless exploration is stepped up, therefore, the more expensive uranium could come into demand at about the same time as the Swedes' suspended nuclear programme would have been—and perhaps will still be—well advanced. Sweden would expect to be a major exporter of reactor fuel elements. But the nuclear issue has caused an extraordinarily vigorous public debate over the past year, focused mainly on the safety aspects and the disposal of nuclear waste. (In fact Sweden neatly solves its radioactive waste problems by sending its reactor fuel elements to Windscale, England, for reprocessing.) More recently the social and security consequences of a nuclear

decision have come into focus. Pronuclear groups have insisted that no rise in the standard of living will be possible without large scale nuclear power, and have pointed out the dangers of dependence on foreign energy sources. Anti-nuclear forces have responded that the choice is not between increased growth and alternative energy sources: both are possible.

The two new reactors proposed by the government are officially justified on the grounds that they, together with increased hydroelectric power, will make up the extra 15 billion kWh of electricity necessary for a projected increase of 2% a year in energy consumption. Non-oil-fired power stations are being emphasised in an attempt to lessen the country's dependence on the Middle East. As the average annual increase in consumption over the 15 years until 1973 was 4.5%, the new projection will certainly test the efficacy of save-energy campaigns. It is hoped that, by 1990, growth in energy consumption will be zero.

As well as changing the relative emphasis on present energy sources, the plan provides money for research into fusion, geothermal, wind and solar power. But the fact that the allocations for this research are roughly only 10% of those for the building of new reactors shows where the government's confidence lies. It will be surprising if, having laid the groundwork so skilfully, the Social Democrats do not use the 1978 review to hasten the day when the Swedes will be the largest users of nuclear energy in the world. □

OECD energy

THE Organisation for Economic Co-operation and Development (OECD) report on the problems and perspectives of energy research and development published earlier this year provides a comprehensive and relatively up to date (September 1974) review of expenditure on all facets of energy research throughout the OECD countries, which include Europe, the United States, Canada, Australia, New Zealand and Japan.

Although the report does not commit itself to specific criticisms of member states' energy research programmes, it obviously feels the need for a longer term approach to the problem, which appears to be lacking in many aspects of energy research programmes set up in response to the 'energy crisis' of 1973. It warns for instance that the sudden upsurge in energy R&D must not be subjected to cutbacks once the most spectacular effects of the crisis have receded and the problem has become less sensitive politically.

In general the distribution of resources should be directed to keeping

as many alternative sources of energy open as possible. Research aimed at energy production should no longer be limited to one primary source. Perhaps the country which has made the largest turnaround is the United States which now supports a massive and diverse programme on every conceivable aspect of energy production but which previously had based its energy policy very largely on the availability of cheap imported oil.

One important and as yet relatively undeveloped field of energy research is energy systems. This covers the inter-relationships between production, transport and use of energy and also takes in any factors which might have a bearing on the smooth functioning of that system, such as effects on the environment and supply of skilled manpower. The use of energy accounting to clarify the energy flow through these systems from the level of primary energy up to the finished product is also encouraged. The study of energy systems, says OECD, can be an extremely important factor in moulding future policies.

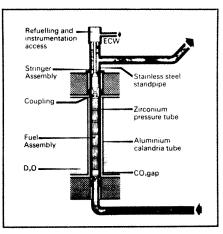
Although the tables of statistics and research programmes are necessarily incomplete and sometimes countries cannot be directly compared as some figures include a measure of industrial research whereas some pertain to government expenditure only, they provide interesting reading. The USA of course leads the field spending over $1,000 million in the fiscal year 1974. France and Germany spent around $350 million and $450 million respectively and the United Kingdom spent around $228 million in 1973–74.

With regard to the organisation of energy policy, the OECD picks out Britain and the United States as the only two countries which have set up a new ministry or agency to deal with the complete problem, thus fixing a policy course that links energy R&D administration with general energy policies. In other countries, energy research has been taken under the wing of the science ministries, where they exist, or handed to some *ad hoc* committee.

Where energy problems can be reduced to matters of technology to be solved by a specific research programme, the outlook seems fairly optimistic. The member states of OECD, comprising as they do the most highly developed industrialised societies, are orientated to cope relatively easily with that type of problem. But energy is an extremely delicate political subject and affects the whole nature of society. Therefore, says OECD, "future development [of energy] will mainly depend on the political decisions of countries with regard to the nature of their economic growth and social structures". □

THE decision made last year that Britain's next commercial reactors should be of the steam generating heavy water type (SGHWRs) has given a predictable fillip to morale at the United Kingdom Atomic Energy Authority's research establishment at Winfrith, Dorset, where the 100-MW prototype has been supplying electricity to the grid for more than seven years. And not suprisingly, a greater proportion of Winfrith's annual spending of £9 million (of which £5 million represents payment for the electricity Winfrith supplies to the national grid) is being channelled into work on the SGHWR, at the expense of some of the establishment's other activities.

The Winfrith SGHWR has the rare distinction of being based on a design for a reactor more than five times its size, which means that scaling up to a commercial reactor of perhaps 660 MW (a size which matches the capacity of the electricity generating equipment now widely used in Britain) should be child's play by comparison with the same exercise for the British advanced gas cooled reactors (AGRs); the AGR programme in Britain is hopelessly behind time and still far from complete.

The secret is that an SGHWR is really a collection of mini-reactors of about 1 MW strung together. As the diagram shows, the basic building block, a pressure tube assembly, is remarkably simple: water at high pressure enters at the bottom and emerges from the top as steam which is fed to the turbines. Put 104 of them together in parallel and you have the Winfrith reactor, or a reactor of almost any desired size by varying the number.


Although Winfrith will continue to be interested in the kind of research that is best carried out on a prototype reactor—testing of new component designs and materials, for example—it will be for the Nuclear Power Company to finalise the design details for the first commercial SGHWR.

Presumably at that time, too, people will start to talk again about the prospects for exporting SGHWRs. Although the potential customers of a few years ago, such as Australia, Greece and Finland, are probably lost, it is at least now possible to say as part of a sales pitch that electricity utilities in Britain are also buying them.

● MORE than a year since energy policy became a hot parliamentary property, the British Secretary of State for Energy, Eric Varley, continues the tradition of the committees under his purview by appearing before Commons sub-committees, armed with good intentions. When he first appeared before the Energy Resources Sub-committee of the Select Committee on Science and Technology, Mr Varley said last year that since he had only been at the job for three months it was early days for him to be formulating hard and fast policy. But he promised he would do his swotting up while listening to all kinds of advice. A little later his Advisory Council on Energy Conservation came before the same sub-committee and said that they too were open to suggestions, though they had precious

Energy in Britain

SGHWR boiling channel

few of their own to offer. Then followed, earlier this year, Varley's new Chief Scientist, Harwell *wunderkind* Walter Marshall, who virtually burst at the seams with enthusiasm while regretting that it was yet, alas, too soon to be expecting any energy blueprint.

Now Mr Varley has made a return appearance before the Commons energy group, who left him with what one Member of Parliament described as a flea in his ear. Which is to say they gave him to understand that they were not entirely bowled over by the progress of the Labour government's energy strategy. Reviewing the state of the game, Mr Varley harped on his December campaign of exhortation once too often for Labour member Mr Ronald Brown. The 'Save It' campaign was 40-year-old thinking, Mr Brown suggested. And the Energy Secretary's plea that people should economise by keeping their refrigerators three-quarters full was "pedestrian".

Mr Brown went so far as to suggest that the energy chief was in thrall to bodies of important chaps who were so busy beavering away at their uncoordinated committees that the whole energy package was turning out to be a "hotch potch". The chosen big-wigs were generally firm about the things which could not be done, but less firm about suggesting what could be done, said Brown, naming Ieuan Maddock (Chief Scientist at the Department of Industry) as the "godfather" of the gang. Mr Brown asked whether or not Mr Varley had the right people on the job (the energy conservation group are in fact part-timers) and the committee chairman, Arthur Palmer, confessed he had the distinct impression that Chief Scientist Marshall had too much on his plate, what with running Harwell and sitting on all those committees.

Not so, replied the Secretary of State, stoutly. Marshall wasn't complaining about overwork, and the advisory boards were manned by chaps with enormous experience. If they didn't appear to be pulling up trees it was worth bearing in mind that only 1% of energy used in the country was under government control, the rest being used by private industries which the government could simply advise. Alas, Mr Varley was leading with his chin. Apparently, one of the Department's advisory groups, the Advisory Council for Research and Development of Fuel and Power (ACORD) has been busying itself with the energy problems of the nationalised industries only, when its brief placed no such restriction on its activities.

When this was pointed out to Mr Varley, along with a suggestion that it was unrealistic to plan national energy policy by investigating only the nationalised concerns, the Secretary of State looked moderately sick and conceded that it was "a very good point" which had not been brought home to him before, and which he would look into.

As for the statistics, which caused him to brighten, at the outset, Mr Varley reported oil imports running recently at a yearly rate of less than 100 million tons, with the likelihood of even lower levels to come. This figure compared with 112 million tons in 1973 and 109 millions tons in 1974. Total energy consumption in 1974 was 4.5% down on the previous year and inland deliveries of oil in January this year were 4% down on the figure for 1974 and nearly 13% less than for January 1973. Petrol consumption, which normally rises at an annual rate of 7% was 5% down last January on the figure for January two years earlier.

But the committee wanted to know how much of this cut-back was positively caused by implementation of the Department of Energy's fuel-saving policy, and how much was caused by the general industrial recession. Not possible to say, claimed Mr Varley, but he promised to have somebody make the attempt. Certainly it can't all have been caused by a sudden overstocking of refrigerators.

correspondence

More on nutrition

SIR,—Since I participated in what Rivers says may have been the "golden age" of nutrition, I feel that I should comment on his indictment (January 10). He says that since 1945, "nutrition in the UK has been neither of military importance nor Nobel Prize ranking." The first circumstance is difficult to deplore since it mainly results from the lack of World War III; the second criticism is tinged with nostalgia. Rivers apparently expects nutritionists to produce miraculous "cures" of "obesity, diabetes mellitus, kwashiorkior, ischaemic heart disease and many of the other great nutritional [sic] scourges." He suggests that the reason that these cures have not appeared is the lack of an experimental animal with an evolutionary defect such as the loss of L-gulonolactone oxidase in the guinea pig. In other words, he thinks that these "scourges" are deficiency diseases awaiting the discovery of an ascorbic acid. But much obesity results from over-eating, only occasionally aggravated by endocrine imbalance; diabetes mellitus comes from hormonal insufficiency; and kwashiorkor from economic, cultural and environmental deprivation. Whether ischaemic heart disease is a nutritional deficiency is not known.

Rivers says that "we do not know why nutrition education fails when advertising works". But, alas, we do and this sentence is the keynote to Rivers' lack of understanding of the predicament of nutrition. This is the day of the nutritional pied piper. The story of scientific nutrition is too humdrum to attract popular attention, at least in the USA, in the fierce light of competition from the writings and speeches of Adelle Davis, Carlton Fredericks, Linus Pauling, Jerome Rodale, Doctor Atkins, R. J. Williams and the brothers Shute who promise relief from heart disease, cancer, infections, prostate trouble, obesity, shortness of life, and back pains by devouring pumpkin seeds, raw milk, dried seaweed, ascorbic acid, fertilised eggs, apricot seeds, vitamin E and garlic, or by not consuming white bread, pasteurised milk and food additives. As Philip White of the American Medical Association says, "what usually happens is that the scientific spokesman ends up sounding like a close-minded Establishment bore who wants to suppress bright new ideas".

Nutritionists wearily spend their time trying to pick up the pieces in the wake of this ideological hurricane. Yes, we know too well that advertising works. Rivers kindly informs us that we "are not in business to pursue uncluttered academic research" (where have scientists heard this before and how does Rivers expect a remedy for ischaemic heart disease without research?) "but to improve the nutritional status of the population", to do which we "don't know how". It sounds as if he doesn't know what he is talking about. One thing we do not need is more Nobel laureates, especially loquacious ones. We have the tremendous task of applying the knowledge of nutrition to the needs of a species that is fantastically eccentric and variable in its attitude towards the acceptability of food, and that is increasingly influenced by nutritional nonsense dispensed by the mass media. The task is made frustrating by the fact that the annual bulk cost for supplying the needed allowances for ten vitamins and eight essential minerals is less than $1 per capita, but for socio-economic political and logistic reasons, we cannot get them to most people. On top of this, we are faced by the awesome world food crisis. There is little helpfulness in Rivers's fuzzy sermonising. There is need for calories and there is no alternative to photosynthesis.

Peaceful explosions

SIR, — That the Non-Proliferation Treaty has defects, to some of which you have drawn attention, is widely accepted, but to adapt a well-known phrase, it is the best treaty we have. Roughly two-thirds of UN states are full parties to the treaty, which requires states to refrain from policies many of them would otherwise actively pursue.

Your particular complaint that nothing has been done to implement the requirements of Article V, that there should be an international organisation for the provision of peaceful nuclear explosions to non-nuclear weapon states, is not strictly correct. On the recommendation of the Conference of Non-Nuclear Weapon States in 1968, the UN General Assembly agreed in 1971 that the International Atomic Energy Agency itself should assume that responsibility. So far Czechoslovakia, Madagascar and Romania have enquired about services,

but a specific proposal is yet to come.

This does not mean that peaceful nuclear explosions will not be a contentious issue at the Review Conference in May, but the issues will be different from those you suggest. Now that Congress has for practical purposes put an end to the Plowshare programme, and as it becomes clearer that the Russian programme of peaceful explosions, however extensive, is yielding disappointing results, the nuclear powers will be tempted to suggest that non-nuclear parties should forego peaceful explosions. Politically that would be dangerous; let non-nuclear states discover economic reality for themselves.

That the treaty is for practical purposes innocent of security assurances for non-nuclear weapon states is true enough, as your leading article says, but it could hardly be otherwise. In practice, the best way of achieving this goal is along the lines of the Latin-American denuclearisation treaty (the Treaty of Tlatelolco, 1967). Indeed, there is good evidence that states unwilling to accede to the NPT will take part in regional arrangements like this. Although the main defect of the treaty is, as you say, that it asks for "minimal concessions" from the nuclear powers, it does require of them rapid progress towards a comprehensive test-ban treaty and measures for the reduction of nuclear stockpiles. Indeed, the NPT is a compact between non-nuclear states and nuclear states in which the former undertake to refrain from "horizontal" proliferation and the latter to pursue nuclear arms control. Much of the argument at the review conference will no doubt hinge on the extent to which the superpowers can fob off their critics with the Threshold Test-Ban agreement and SALT II. Probably they will not succeed. There will be pressure for more effective means of monitoring the super-powers than five-year reviews provide.

Precisely for this reason, the NPT is a potentially important forum within which measures of nuclear arms control can be developed. At the same time, there are many significant ways in which the inequalities of the treaty can be softened, not necessarily within its legal structure. To "suggest the treaty be scrapped and new approaches tried" is to run the risk of setting back arms control for a decade or more.

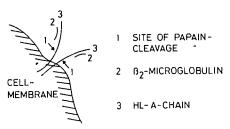
Excitement over β₂-microglobulin


from Martin C Raff

FROM its meagre beginnings in 1968 when it was isolated from the urine of patients with renal tubule dysfunction (Berggard and Bearn, *J biol Chem*, **243**, 4095), β₂-microglobulin has rapidly blossomed into a molecule of great interest and importance to immunologists It is synthesised and secreted by most nucleated cells of vertebrates (Nilsson *et al*, *Nature new Biol*, **244**, 44, 1973) and is also present on the surface of these cells, as well as in the urine, serum (1–2 mg l⁻¹) and other body fluids Although its function is still unknown, recent observations have markedly sharpened interest in this ubiquitous protein by suggesting an evolutionary link between β₂-microglobulin, immunoglobulin (Ig) and the major histocompatibility (H) antigens

The complete amino acid sequence of human β₂-microglobulin has been determined and shows a striking degree of homology with the constant domains of human IgG (Cunningham *et al*, *Biochemistry*, **12**, 4811, 1973) It has 100 amino acid residues, a molecular weight of about 11,500, a single intrachain disulphide bond which forms an intrachain loop of similar size to those seen in the homology regions of Ig, and contains no carbohydrate These findings led to the suggestion that β₂-microglobulin represented a free Ig domain with effector function similar to the terminal domain (C_H3) of IgG, which it resembles most closely (Peterson *et al*, *Proc natn Acad Sci USA*, **69**, 1697, 1972)

Two independent lines of evidence have indicated that β₂-microglobulin is an integral part of the subunit structure of all the membrane proteins that carry the serologically defined major histocompatibility antigens (H-2 in mouse HL-A in man) on the surface of virtually all normal nucleated cells When HL-A (Cresswell *et al*, *Proc natn Acad Sci USA*, **70**, 1603, 1973, Tanigaki *et al*, *Immunology*, **26**, 155, 1974) and H-2 (Rask *et al*, *Nature*, **249**, 833, 1974) antigens are solubilised by detergent or proteolytic enzyme treatment of cells, they are found to be composed of a heavy chain (~34,000 or 44,000 daltons depending on whether papain or detergent is used respectively)

and a light chain (~12,000 daltons) which appears to be identical with β₂-microglobulin There is evidence that both HL-A (Strominger *et al*, *Transplantn Rev*, **21**, 126, 1974) and H-2 (Rask *et al*, *Transplantn Rev*, **21**, 85, 1974) are four-chain structures in the membrane, with two heavy chains covalently linked by disulphide bonding between their hydrophobic tails, and the two β₂-microglobulin molecules non-covalently bound to the heavy

2	β₂-MICROGLOBULIN
3	HL-A-CHAIN

Rask's tentative picture of an HL-A molecule in the cell membrane (from *Transplantn Rev*, **21**, 102, 1974)

chains, a structure remarkably similar to Ig Characterisation of solubilised H antigens in guinea pig (Finkelman *et al*, *J exp Med*, **141**, 27, 1975), rat and rhesus monkey (Tanigaki and Pressman, *Transplantn Rev*, **21**, 15, 1974) have suggested that the β₂-microglobulin–H association is a basic feature of H antigenic molecules in mammals

A different approach to determining associations on the cell surface involves the binding of multivalent ligands (such as antibodies) to specific determinants (antigens or receptors) on the surface of intact cells to induce their redistribution into 'patches' or 'caps', and then studying the distribution of other membrane determinants In such co-capping experiments, most antigens and receptors that have been studied redistribute independently an exception being that all the HL-A antigens on human lymphocytes (Poulik *et al*, *Science*, **182**, 1352, 1973, Solheim and Thorsby, *Tissue Antigens* **4**, 83, 1974, Ostberg *et al*, *Nature*, **249**, 463, 1974, Neauport-Sautes *et al*, *J exp Med*, **139**, 957, 1974) and other cell types (Solheim, *Transplantn Rev*, **21**, 35, 1974) co-cap with β₂-microglobulin when the cells are treated with anti-

β₂-microglobulin antibodies These experiments make it clear that the association of solubilised HL-A with β₂-microglobulin in not an artifact of the solubilisation and/or separation procedures Capping HL-A with anti-HL-A antibodies fails to cap all of the β₂-microglobulin, suggesting that not all of the β₂-microglobulin is associated with HL-A

Although β₂-microglobulin occurs free in the serum, its structure makes it unlikely that it can be bound in the membrane other than by interacting with other membrane proteins In mice two other plasma membrane proteins recently have been found to be associated with β₂-microglobulin, the thymus leukaemia (TL) antigens (Ostberg *et al*, *Nature*, **253**, 735, 1975), which are restricted to thymus lymphocytes and lymphoma cells, and the teratocarcinoma alloantigen(s) (Artz and Vitetta, personal communication), which is restricted largely to early cleavage and morulae stages of mouse embryos, spermatozoa, and teratocarcinoma cells It is interesting that both of these alloantigens are determined by genes that are closely linked to the H-2 complex

On the other hand, not all alloantigens coded for by genes in the H-2 complex are associated with β₂-microglobulin, the Ia (immune response associated) alloantigens, determined by genes in the IR region of the H-2 complex, seem not to be associated with β₂-microglobulin In those cases where membrane polypeptides are normally associated with β₂-microglobulin, it is unlikely that β₂-microglobulin is required for their insertion or maintenance in the membrane This is suggested by the finding that a human lymphoblastoid cell line from a patient with Burkitts' lymphoma (Daudi) does not synthesise β₂-microglobulin or have it on its surface and yet probably carries the heavy HL-A polypeptide chain on its plasma membrane (Rask *et al*, *Transplantn Rev* **21**, 85, 1974) But it is possible that the β₂-microglobulin serves to stabilise the functional conformation of these polypeptides (whatever their function turns out to be) The structural linkage of β₂-micro-

globulin with a variety of membrane proteins controlled by genes in or near the major histocompatibility complex raises the question of whether the gene for β_2-microglobulin is also located in this chromosomal region The report by Goodfellow *et al* (*Nature,* **253**, 267, 1975) indicates that in man at least it is not By studying a variety of human–mouse somatic cell hybrids they found that cells carrying human chromosome 15 expressed human β_2-microglobulin on their surface, while cells not containing this chromosome did not, in a line which carried chromosome 15 as the only human chromosome, human β_2-microglobulin was expressed Since the HL-A complex has been assigned previously to chromosome 6, it seems virtually certain that in man, the β_2-microglobulin and HL-A genes are unlinked

Despite the apparent lack of genetic linkage, the physical association of β_2-microglobulin with H or H-linked, membrane-bound gene products is intriguing Taken together with the striking homology in structure between β_2-microglobulin and some Ig domains, it suggests the possibility that β_2-microglobulin, Ig and possibly these histocompatibility-linked genes have evolved from a common ancestral gene The association of unlinked but evolutionarily related gene products to form a membrane subunit protein has a well established precedent in membrane bound Ig, where unlinked light (L) and heavy (H) chain gene products make up the subunit molecule H_2L_2 Since membrane-bound Ig is known to function as an antigen-specific receptor on B lymphocytes, it may be that these other membrane molecules also have some kind of recognition or receptor role

In the case of Ig both L and H chains have separately coded constant (C) and variable (V) regions, with V_L and V_H both contributing to the antigen-combining site, thus the multichain structure serves the obvious purpose of greatly increasing the potential number of combining sites that V_L and V_H gene products can form Since there is no evidence for variability in the structure of β_2-microglobulin, the grand purpose of the H–β_2-microglobulin multichain structure remains a mystery Unfortunately, very little is known about the structure of the histocompatibility heavy chains, and the possibility of their having separate constant and variable regions, or regions homologous to Ig domains $\pm$ β_2-microglobulin, remains open

The gene products of the H complex are mainly cell surface proteins, many of which are involved in various immune responses, particularly T lymphocyte responses, such as graft rejection, graft-versus-host responses, mixed lym-

phocyte reactions, cell mediated lymphocytotoxicity and other specific immune responses to a variety of antigens Although the nature of the antigen-specific T cell receptor(s) remains controversial, and although it is not known how these H-complex gene products function, the physical association of β_2-microglobulin with some of these surface proteins provides a suggestive evolutionary link between B cell-mediated humoral immunity and T cell-determined cell-mediated immunity The possible immunological importance of some of the lymphocyte membrane proteins associated with β_2-microglobulin is underlined by the recent findings that anti-β_2-microglobulin antibodies inhibit various T cell responses (Solheim, *Transplantn Rev* **21**, 35, 1974) and are mitogenic for B cells (Maller and Persson, *Scand, J Immun,* **3**, 100, 1974)

It is not surprising that immunologists are excited about β_2-microglobulin

Element 106 and onwards?

from C J Batty

THE recent announcements by both Soviet and American teams of the discovery of element 106 is not only a further chapter in the saga of rival claims to be first but raises the interesting question as to how many other elements remain to be discovered, and in particular, what are the chances of producing superheavy elements

To some extent the rival claims are due to the differences in techniques used by the Soviet and American workers G N Flerov and his co-workers at the Joint Institute for Nuclear Research at Dubna near Moscow have generally used nuclear reactions involving fairly heavy ions and have looked for spontaneous fission activity On the other hand A Ghiorso and the team at the University of California, Berkeley, San Francisco have used heavier targets such as Californium, lighter incident ions and have made very detailed studies of the resulting α-activity In both cases the techniques are difficult and the resulting activities short lived, with typical half lives of a few seconds or less As a sign of the rival claims elements 104 and 105 have been christened Rutherfordium and Hahnium in the USA and Kurchatovium and Nielsbohrium in the USSR Perhaps in an atmosphere of detente, element 106 so far remains unnamed

Details of the Soviet work so far seem to be only available in unpublished reports but it involves the use of a radically different reaction method Rather than using the heaviest target material available they instead chose lead The nucleus ^{208}Pb has the advantage that it has 'magic' numbers

of both neutrons and protons and as a result the compound nucleus formed may have a low excitation energy This leads to a decrease in the number of neutrnos emitted and an increase in the cross section for forming the residual nucleus in its ground state The use of lead rather than fissile material also helps in reducing unwanted background activities The technique has been very successfully used by the Dubna group (*Nuclear Physics*, A239,. 157, 1975) in producing two new isotopes of element 104 using the ^{208}Pb $(^{50}$Ti,2n) ^{256}104 and ^{207}Pb$(^{50}$Ti,2n$)^{255}$104 reactions In the work on element 106 they used a beam of ^{54}Cr ions and the team believe they have seen the ^{208}Pb$(^{54}$Cr,3n$)^{259}$106 reaction with the final nucleus decaying by spontaneous fission with a half life of between 4 and $10\,\text{ms}^{-1}$

The work at Berkeley (*Phys Rev Lett*, **33**, 1490, 1974) used a ^{249}Cf target, as in the previous experiments on elements 104 and 105, together with a beam of ^{18}O ions from the 'SuperHILAC' accelerator to study the ^{249}Cf$(^{18}$O,4n$)^{263}$106 reaction Using a sophisticated system of α-detectors linked to an on-line computer they not only observed the α-decay of ^{263}106 with an energy of 9 06 MeV and half life of $0\,9 \pm 0\,2$ s but also observed the α decay of the daughter nucleus ^{259}104 $(t_{\frac{1}{2}} = 3$ s, $E\alpha = 8\,8$ MeV) and of the grand-daughter ^{255}No $(t_{\frac{1}{2}} = 3$ min, $E\alpha = 8\,1$ MeV) so establishing the decay sequence

$$^{263}106 \xrightarrow{\alpha} {}^{259}104 \xrightarrow{\alpha} {}^{255}\text{No} \xrightarrow{\alpha}$$

With very small cross sections for forming these very heavy nuclei together with their short half lives for decay it is clearly going to be difficult to go to the even heavier elements But it is understood that the Dubna team are now trying to produce other isotopes of element 106 using their new technique and may attempt to synthesise elements 108 and 110 using beams of ^{58}Fe and ^{64}Ni ions No doubt the Berkeley team have their own plans for work in this tough but exciting field

Which leaves us with the question of the superheavy elements These are an island of elements with atomic numbers in the region of 114 which owe their possible existence to the extra binding energy associated with the closed nucleon shells at 114 protons and 184 neutrons Prediction of their half lives for decay is difficult but some theories have suggested values sufficiently long to warrant searching for them in natural materials on Earth (*Nature phys Sci*, **246**, 26, 1973) so far generally without success

One problem with trying to produce these superheavy nuclei using the techniques employed for the 104 to 106 region is their very large neutron excess so that for example ^{298}114 cannot be obtained by the complete fusion of any real combination of target and projectile Nevertheless the Dubna group have reported (*Sov J nucl Phys* **19**, 123, 1974, *Sov J nucl*

Phys **19**, 247, 1974) experiments using beams of Zn and Ge ions, the latter being accelerated by a tandem arrangement of two cyclotrons Looking for spontaneous fission activity with an experimental arrangement which permitted high sensitivity, the teams were unable to find any evidence for the production of superheavies It seems that further work will require even more sensitive experiments and higher intensity beams of energetic heavy ions

Solar gravitational deflection of radio waves

from J M Riley

SINCE the publication of Einstein's general theory of relativity in 1916, there have been many attempts to test the prediction of this theory that electromagnetic radiation is deflected in the gravitational field of the Sun The experimental test of the prediction involves measuring the change in the apparent position of a star when it is close to the Sun The effect is extremely small as the predicted deflection amounts to a maximum of 1 75 arc s, for a ray path from a star which grazes the limb of the Sun, and decreases inversely with distance from the centre of the Sun A very accurate measurement of this deflection is required as it is clearly of fundamental importance to find out how closely general relativity agrees with observation and to test its predictions against those of other theories of gravitation Among the alternative theories which have received serious consideration is the Brans–Dicke scalar–tensor theory which, in its latest form, predicts that the deflection is 0 94 times that predicted by general relativity

Until ten years ago the only tests had been carried out optically during total solar eclipses and, owing to great technical difficulties, had provided only semi-quantitative support for general relativity with accuracies of about 25% Recently however it has become possible to perform the experiment at radio wavelengths using the technique of interferometry, in which the position of a radio source may be found by measuring the difference between the time of arrival of signals from the source at two radio antennae some distance apart on the Earth's surface, this method involves knowing with great precision the time at which the signals are recorded at each antenna An experiment of this type has been performed several times since 1969 using the QSO 3C279 which passes behind the Sun in October every year,

it may be observed for several days before and after this when it is very close to the Sun The change in its apparent position is measured relative to that of another source, 3C273, which is close to it in the sky but sufficiently far from the Sun during the experiment to be unaffected by the gravitational deflection

The first tests of this kind were made using antennae separated by relatively short distances (from 1 to 5 km) operating at frequencies between 2,700 and 8,000 MHz, it was therefore possible to have direct electrical connection between the antennae and consequently it was relatively easy to standardise the time of the observations at the two antennae The most accurate experiment of this type gave a result 0 96±0 05 times the value predicted by general relativity

It is also possible to carry out the experiment using antennae several hundreds of kilometres apart In such an experiment the difference between the time of arrival of signals at the two antennae is proportionately greater than in the shorter baseline experiments and in principle therefore the experiment should be much more accurate But in a long baseline experiment, direct electrical connection between the antennae is impossible so that independent clocks must be used at the two sites, due to instabilities in these clocks there is then a problem standardising the time of the observations at the two antennae Furthermore, as the two sites are so far apart there are likely to be very significant differences in the path lengths through the atmosphere of the radiation arriving at the two antennae

In a recent paper in *Physical Review Letters* (**33**, 1621, 1974) Counselman *et al* describe the first results of such an experiment performed in October 1972 using a baseline of 845 km and a frequency of 8,000 MHz In this experiment the problem of the differences between the independent standards used at the two sites was overcome by using a pair of antennae at each site, one directed at 3C279 and the other at 3C273 A single clock governed the recording of the signals received by both antennae at a given site, the difference between the time of arrival of the signals from 3C279 at the two sites could then be measured with reference to that between the time of arrival of the signals from 3C273 at the sites, thereby eliminating the effects of any clock instabilities at either place This method also reduces the effects of any differences in the atmosphere and ionosphere above the two sites In analysing the data it was necessary to assume models for the atmosphere, ionosphere and the solar corona, and uncertainties in these models, particu-

larly in that for the corona, contribute about half the error in the final result. The remaining error is attributed to experimental difficulties, in particular those introduced by fluctuations in the solar corona The observed deflection was 0 99±0 03 times the value predicted by general relativity This measurement is probably the most accurate yet made of the gravitational deflection of radiation and the result is in close agreement with general relativity, it is slightly more than one standard deviation from the value predicted by the Brans–Dicke Theory

The prospects for improving the accuracy of this test of general relativity using the method of very long baseline interferometry are good, as it is possible to eliminate several of the problems encountered in the experiment mentioned above by making simultaneous observations at two frequencies It is likely that accuracies better than 1% may be achieved in the very near future

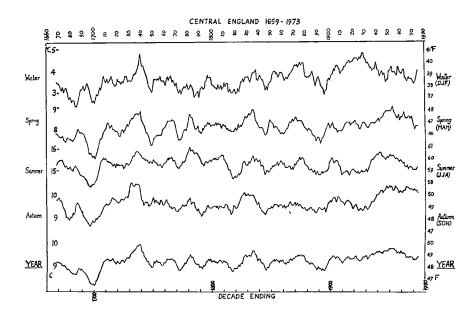
A hundred years ago

WHITE'S "SELBORNE"

White's Natural History of Selborne Edited by J E Harting, F L S Illustrated by Bewick (London Bickers and Co, 1875)

ALTHOUGH we have no evidence that, within the last century, there has been any considerable change in the average standard of human mental power amongst civilised nations, the surroundings of every day life have so greatly altered, both in their quality and in the rapidity of their occurrence, that the standard of ordinary existence has undergone a corresponding modification The introduction of steam loco motion, the electric telegraph, and the penny post have developed such a condition of unrest in humanity at large that the unalloyed repose of a continuous rural life is rarely sought for, and as infrequently obtainable We can hardly conceive it possible that anyone, such as a life-fellow of a college, as was Gilbert White, of Oriel, Oxford, should at the present day settle down in any out-of-the-way part of the country, satisfied with nothing more than an opportunity of observing and recording the surrounding phenomena of nature More would be expected of him, and he would be continually led to feel that he was but one of the instances of the vegetating influence of an antiquated system, whose advantages were being daily disproved by his individual existence

from *Nature*, **11**, 423, April 1, 1875

Causes of climatic change


M K Miles of the Meteorological Office reviews the recent evidence while (below) John Gribbin reports on a lecture which may have helped to draw fresh ideas to the field

Decadal running averages of seasonal and annual mean temperatures, from Manley, *Q J R Met Soc*, **100**, 402, 1974

FROM 1880, when the first reasonably reliable determination of the average temperature of the Northern Hemisphere was possible, there has been a warming (with only minor reverses) until 1940 and since then a cooling In both cases the effect has been most marked north of about 70°N latitude and in the winter half of the year From the 300-year-long temperature series prepared by Manley (*Q J R Met Soc*, **100**, 389–405, 1974) for central England it could be said that winter temperatures have been rising since the end of the seventeenth century, at a rate of 0 36 °C per century with reverses lasting several decades This temperature series indeed shows fluctuations on all time scales but there seem to be no clearly marked periodicities (see figure)

Possible effects of sunspots

Many investigators have sought a relationship with the various periodicities displayed by sunspot activity, and although for some records and some seasons statistically significant results have been obtained, there are also contradictory results If there is a real relation with the 11-year sunspot cycle it is a complicated one, changing its phase relationship from epoch to epoch, but in any case not accounting for a very substantial amount of the variance at that time scale The same applies to the double sunspot cycle (successive 11-year cycles showing opposite magnetic polarity of the sunspots)

A relation with a longer cycle of solar spot activity varying between 60 and 100 years has been claimed, but the amplitude of the response is small and not clearly above the play of chance There is naturally even less convincing evidence for a suggested periodicity of 180–200 years related to a solar cycle whose length and physical characteristics are not well established The ¹⁸O record from the Camp Century ice core has been adduced as evidence for periods of 77 and 177 years, but adjustments were made to the time scale to preserve persistent climatic oscillations so it is not entirely independent evidence Even so the record is substantially out of step with the

Manley temperature record for central England in the eighteenth and nineteenth centuries The variations of ¹⁴C content in dated wood specimens have been claimed to show 200- and 400-year periodicities, but the experimental error in the ¹⁴C determinations means that such a claim should be accepted with great reserve

It is still not certain that the heat output from the Sun varies enough with changes in the number of sunspots to affect the lower troposphere Satellite measurements indicate large changes in the ultraviolet part of the spectrum at different times during the 11-year sunspot cycle, but the fraction of the total energy in this part of the spectrum is very low To date satellites have not monitored changes in the spectral range 0 3 to 1 0 μm

Terrestrial influences

Other factors thought capable of producing changes in the lower troposphere are dust (volcanic and wind erosion dust), CO_2, water vapour and changes in ocean temperature and salinity Increasing CO_2 from burning of fossil fuel is generally estimated to be capable of explaining a substantial part of the warming since 1880, and a clearer stratosphere resulting from fewer volcanic eruptions in the twentieth century compared with the eighteenth and nineteenth would be expected to act in the same sense If this be so then a strong cooling factor must have come into play since 1940 The first major eruptions after Katmai in 1912 did not occur until the early 1950s, so a sudden increase in dust from other sources (and aerosol loading) has been postulated Measurements of the electrical conductivity of the air over

the Atlantic indicate an increase in the number of Aitken nuclei in recent years compared with the early 1930s but the data are not adequate to show whether this happened around 1940 or not On the other hand direct solar radiation measurements as collated by Budyko and Vinnikov (*Glav, Uprav Gidromet, Sluz, Met Gidr*, **9**, 3–13, 1973) do not reveal a substantial drop until about 1945 The dust from semi-arid zones in America and the Soviet Union which one would expect to have increased following the dry conditions of the 1930s does not seem to have affected radiation

Aerosols from increasing industrial activity and changing agricultural practices are probably the most likely agents to have contributed to the fall in direct solar radiation said to have occurred since 1945 There are, however, two factors to be considered before it may be concluded that the cooling is due to this First, the aerosol being largely in the troposphere will often lie below cloud top, and does not have a long residence time in the atmosphere Second, it may absorb radiation as well as reflecting it so that the net cooling effect may be very small However, it must be said that attempts to determine the secular change of atmospheric turbidity do not all support an increasing global trend either for the time since the late 1950s or for the century

Quite small variations in the global cloud cover are capable of altering the heat balance substantially but data are not adequate to reveal any long term trend Similarly data about ocean temperature and salinity are not adequate to assess the part the oceans might have played in the warming and subsequent cooling Minor changes in

oceanic circulation are capable of leading to substantial changes in the heat exchange with the atmosphere

The area of ice and snow cover in the polar regions decreased between 1900 and 1930, then began to increase in the late 1950s One school of thought attributes the increase to the lower direct heat input since about 1945, but the decline in the Atlantic winter circulation in the last two to three decades could perhaps have produced the same effect There is even some evidence that a further change occurred about 1970 The area of sea ice was less for the four years 1971–74 than for the preceding four years Again there has been a change in the Atlantic winter circulation but it is noteworthy that Budyko in an updating in 1973 of his direct radiation index shows an increase setting in during the late 1960s

Other atmospheric variation

Changes in precipitation have also received attention—local changes as well as regional distribution—and various claims have been made for periodic fluctuations The supporting evidence has not however been strong enough to lead to a consensus of

opinion For example the 22 years of the double sunspot cycle is claimed (and widely accepted) to be related to the incidence of droughts over the plains of the American Middle West but data for the steppe and forested zones of the Soviet Union do not show the same pattern

Fluctuations in the strength of the general wind circulation in the Northern Hemisphere broadly parallel the temperature behaviour though there is an indication of a lead of about 10 years—the peak in the hemispheric westerlies for the latitude band 35–55°N being reached by 1930 The North Atlantic winter circulation which displays these changes to a marked degree certainly declined after 1930 whatever latitude band is examined It is difficult to relate these or the smaller scale variations in a sensible way with changes in the temperature gradient between the tropics and the pole or suspected changes of the meridional heat flux Only a small fraction of the internal energy of the atmosphere is converted to kinetic energy and so there is no reason to expect a simple relation between energy input and circulation energy

The reality of strictly periodic fluc-

tuations in the Earth's climate being to some extent in doubt and trends in various parameters being either doubtful (as for example turbidity) or not yet distinguishable from random fluctuations, satisfactory predictions for the next few decades cannot be made Perhaps all that is justified are estimates of the range of possible future fluctuations based on past climatic data together with assessments of the influence of human activity on the surface of the Earth and the composition of its atmosphere

Protecting damaged plant life of Galapagos

from Peter D Moore

THE impact of man and his domesticated animals upon the unique flora and fauna of the Galapagos Islands has been the source of considerable concern in recent years Schofield (*Biol Cons*, **5**, 48, 1973) considered that many endemic trees and shrubs, such as *Scalesia pedunculata* and *Miconia robinsoniana*, were threatened both as a

---

On March 10, Dr Peter Wright (University of East Anglia) spoke at the University of Bristol about climatic change to an audience of mixed physical scientists He emphasised that climate is always changing, on many timescales, and that these changes occur globally A disturbance of climate in one part of the world will affect the whole system, with possibly drastic repercussions on the other side of the globe But man's direct influence on climate, through heating of cities, for example, seems insufficient to disturb the global machinery The kind of disturbance cited by Wright as important would be about 1,000 km across and persistent—paving over the interior of Brazil, say, or smaller and more energetic, but persistent—exploding a nuclear device in the same spot every day for ten years So it is still the study of 'natural' climatic fluctuations which is of key importance

Wright dismissed most of the proposed natural causes of change as minor contributors Solar variations (over the sunspot or longer cycles) could play a part, but are unlikely to dominate to the extent of causing ice ages, the Milankovitch theory that changes in the Earth's orbit and inclination affect insolation enough to cause ice ages seems more tenable (especially now that the geological record has been re-

New climatologists begin here

interpreted to give a better guide to the variations of glaciation over the past few million years), dust in the atmosphere from volcanoes or blown away from eroded and desert areas is a good candidate for irregular effects, but is difficult to reconcile with cyclic changes in climate (if, that is, you believe that climatic changes are cyclic, which Wright does not), geomagnetic fluctuations could, says Wright, 'just conceivably' play a small part (others might argue that by varying the flux of cosmic rays reaching the atmosphere such changes in magnetism could be of greater importance), and man's influences have certainly not been important as yet

All of these processes are forcing effects, Wright, however, believes that, although such variations may make conditions more suitable for, say, icier conditions, it is feedback that maintains any climatic regime

For example if a patch of ocean in the northern hemisphere becomes warmer than average, the effect will tend to be to shift the circum-hemispherical wind streams so that instead of blowing from west to east across the warm patch they swing

up from the south-west, pass around the north of the warm patch and swing away to the south-east The effect is to bring warmer air over the 'anomaly', tending to maintain its warmer state

A more realistic example of a feedback system is the "Southern Oscillation", in which a patch of ocean along the equator just west of the Americas fluctuates between a colder and less cold state (the difference is no more than 3 °C) with associated changes in the pattern of trade winds Each state seems stable, and each is maintained by feedback between wind and ocean systems Why should the situation ever change? Clearly there are external factors involved, even in the rest of the air–ocean system, and computer modelling is far from the stage of sophistication where all these effects are included

As Wright pointed out, climatology today is still to a great extent in the data gathering stage, but already many data are available for analysis and more physical ideas are needed for testing both in the real world and in the models—and this is where there seems to be scope for new talent Outsiders with experience in fluid mechanics, thermodynamics, statistical interpretation of noisy data and so on could play a vital part in the interpretation of the data as they are collected

result of intensive clearance and cultivation of upland areas and because of the spread of exotic plant species introduced by man (see *Nature*, **242**, 299, 1973) Davies (*Nature*, **249**, 788, 1974) pointed out the threat to the islands' flora presented by feral goats and the problems in carrying out scientific research and conservation on the inadequate budget of the Charles Darwin Research Station Can one be sure that the demise of the Galapagos flora and fauna will even be recorded adequately?

A research programme to monitor habitat changes in the islands was instigated by the research station in 1966 Permanent plots of between 6 25 m² and 100 m² were established on several islands in habitats which were thought to be threatened, and recordings have been made since that time of vegetational changes within the plots Hamann (*Biol Cons*, **7**, 37, 1975) has now presented some of the data emerging from this study over the period 1966–73

The arid zone vegetation has suffered to different degrees on the various islands On Pinta, where goats have in the past been a most serious pest, the denudation of vegetation has been severe, sometimes resulting in soil erosion Recent reduction in goat population density has not yet resulted in any marked recovery of the vegetation There is however cause for optimism in view of the regeneration which has been noted on Santa Fé, where feral goats were exterminated in 1971 *Cordia lutea, Encelia hispida, Lantana peduncularis* and *Scalesia helleri* are all recovering in the arid zone of this island since the cessation of grazing One might hope that regeneration will occur in Pinta also, if goat populations can be further reduced

The *Scalesia pedunculata* forests of Isla Santa Cruz, although badly affected by grazing and clearance, seem to have the capacity for rapid recovery and growth under suitable conditions Recent intensive hunting of introduced mammals by National Park wardens may be responsible for the observed increase in saplings of *Scalesia* within the plots However, cattle seem to be very partial to young *Scalesia* trees, so full recovery can only occur if cattle grazing is controlled Exclosure plots could supply the answer to this

Perhaps the most sensitive vegetation type of the Galapagos is that dominated by *Miconia robinsoniana* with *Cyathea weatherbyana* Much of this zone has been damaged by burning, followed by cattle grazing, and this has resulted in its replacement by ferns, particularly *Pteridium aquilinum* It may be that recent prolonged droughts have also contributed to the failure of regeneration in *Miconia* This vegetation type will undoubtedly provide the most difficult conservation problem of all on the Galapagos It has almost disappeared from San Cristóbal and is failing to recover on Santa Cruz, its only other station Protection of the zone from further burning and grazing must be regarded as a management priority

The control of introduced mammals on the Galapagos has proved possible and worthwhile It is to be hoped that funds will be found to continue and intensify this programme of conservation and that schemes can be initiated which will satisfy the needs of both farmer and conservationist on the islands

Long period of lunar crater formation

from Peter J Smith

ONE of the hopes not entirely fulfilled by the Apollo missions was that it would be possible to recover a significant number of lunar rocks older than 4,000 million years As terrestrial rocks of corresponding age have never been found, some workers had hoped that access to lunar material would enable important light to be thrown on the first 500–600 million years' evolution not only of the Moon itself but also of the Solar System particularly the Earth Unfortunately, most lunar mare and highland basalts dated radiometrically appear to be between 3,950 and 3,130 million years old It is true that some highland rocks, notably the cataclastic anorthosites, have yielded ages much closer to that of the Solar System, but some doubt has been expressed as to what such great rock ages really mean The difficulty is that much of the lunar regolith in the appropriate regions represents ejecta from the major basins, material which has been severely shocked, and it is not entirely clear just how shock affects a rock's radioactive properties

Recently, however, Gooley *et al* (*Geochim Cosmochim Acta*, **38**, 1329, 1974) described an unshocked troctolite (Apollo 17) comprising plagioclase, olivine and bronzite, which they conclude cooled at a rate of a few tens of degrees per million years at a depth of 10–30 km Two whole rock samples and a plagioclase separate from this material have now been dated by Husain and Schaeffer (*Geophys Res Lett*, **2**, 29, 1975) using the ^{40}Ar-^{39}Ar technique Extensive tests and close agreement between the ages obtained from all three samples convince Husain and Schaeffer that the accurate mean age of the troctolite is 4,260±20 million years

The corresponding ^{38}Ar/Ca cosmic ray exposure age is 156±8 Myr, suggesting that the troctolite was last brought to the surface comparatively recently The much older ^{40}Ar-^{39}Ar age, on the other hand, supports the major conclusion from Gooley and his colleagues that the rock was originally a product of large scale igneous processes which formed the early lunar crust The combined evidence from petrography and the Ar systematics is that the troctolite probably formed about 4,500 million years ago and then cooled very slowly at depth for tens to hundreds of millions of years During most of this phase the temperature was apparently sufficiently high to make the rock an open Ar system But for the past 4,260 Myr the rock has evidently been a closed Ar system, thus enabling one to date the time at which it was excavated from depth and reburied under an ejecta blanket

This is the simplest and most reasonable chronology consistent with the available data But Husain and Schaeffer believe that they can go even further in relating the rock's history to named events on the Moon For (shocked) lunar breccias from Apollos 14–17, the histogram of measured ^{40}Ar-^{39}Ar ages (see, for example, Schaeffer and Husain, *Geochim Cosmochim Acta*, Suppl **4**, 1847, 1973) covers the range 3,900–4,260 million years and is sharply peaked at 3,900–4,000 Myr As the breccias were almost certainly formed by impacts on the lunar surface and as extensive Imbrium ejecta exist at the Apollo 14–17 landing sites, the histogram peak strongly supports the view that the Imbrium event occurred between 3,900 and 4,000 million years ago

If this is so, the older breccias (assuming their measured ages to be reliable) and the Apollo 17 trocolite must be related to earlier events As far as the trocolite is concerned, the impact which excavated it is now identified by Husain and Schaeffer as the Serenitatis event, largely because the Apollo 17 site lies at the rim of the Serenitatis basin If this is correct, it follows that the age of the Serenitatis is probably 4,260 Myr, the age of the troctolite This, in turn, suggests that what Husain and Schaeffer term the "lunar basin forming era" lasted at least 300 Myr (Serenitatis–Imbrium) In fact it may have lasted much longer because the Serenitatis impact event was preceeded by the Fecunditatis, Tranquillitatis and Nubium events In any case it now appears that these major lunar basins could not all have been formed in a relatively short time about 4,000 million years ago, as some workers have suggested

review article

Schlieren experiment 300 years ago

J. Rienitz*

Schlieren techniques for making visible density gradients in transparent media seem to be older than had been supposed. Robert Hooke developed a method of this kind as early as 1672 but, unlike Christian Huygens, who described a similar technique in 1685, obviously aroused no interest.

DURING the long decades of his activity as Curator of Experiments of the Royal Society of London, Dr Robert Hooke (1635–1703) developed a large number of ideas, experiments, and instruments in the fields of science, technology, and medicine[1,2] Lack of time to elaborate many of his ideas, undeserved discredit, the change in the conception of scholarship during the Newtonian Age, and rivalries in the edition of his bequeathed papers have meant that much of his work has remained unknown One of his unrecognised achievements seems to have been the development in 1672 of a true schlieren method Commonly, it is Léon Foucault (1859) and August Toepler (1864) who are regarded as the discoverers of this group of techniques[3,4]

After the invention of the microscope and the telescope at the beginning of the seventeenth century activity in the field of optics became widespread Refraction was investigated thoroughly, methods for improving the lenses as well as the performance of the optical instruments in general were sought, and the reflections of scholars on the nature of light began to gain impetus Hooke's interest in astronomical problems, as well as in the mechanics of gases, led him to investigate atmospheric refraction He treated it extensively in Observation LVIII of his famous *Micrographia* of 1665 together with a number of related phenomena, writing, for example, "This I have likewise often observ'd in a hot Sunshiny Summer's day, that looking on an Object over a hot stone, or dry hot earth, I have found the Object to be undulated or shaken, "[5] His explanation is quite correct "a multiplicate refraction, caused by the unequal *density* of the constituent parts of the *medium,* whereby the motion, action or progress of the Ray of light is hindred from proceeding in a streight line, and *inflected* or *deflected* by a curve"[5]

These density gradients in a transparent medium are termed streaks Hooke mentions streaks in gases and vapours, in fluids, and in solids The unequal refraction which is the consequence of the unequal optical density is barely visible to the naked eye, and hence the development of schlieren techniques which enhance the contrast Robert Hooke mentioned his schlieren set-up first when he was treating the combustion of a candle as a part of his extensive but often overlooked[1,6] investigations on the nature of combustion, in the course of which, incidentally, he clearly realised the function of oxygen[1] The experiment was performed by Hooke before the Royal Society on February 22, 1671 old style (or March 4, 1672, Gregorian calendar) "to shew, that, besides the flame and smoke of a

candle there is a continual stream rising up from it, distinct from the air"[7] A week later, the experiment "was repeated and proved satisfactory"[7] Finally, on March 14, Hooke submitted an account of the experiment which was registered[7] Here, he describes first the method (For sake of clarity the notations of the illustration are inserted in the following original text in square brackets)

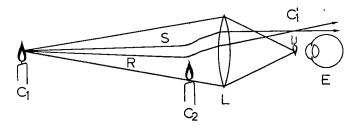
"I took a large concave reflecting glass, or a large convex refracting glass [L], and so placed in respect to my eye [E], that a candle [C₁] set at a certain distance beyond the refracting glass, or between the eye and the superficies of the reflecting glass, enlightened the whole area of the said glasses in respect to the eye Then continuing to keep the eye in that place, where the area of the said glasses appeared to be wholly filled with the flame of the candle, I caused another candle [C₂] to be placed very near the said glasses, between the eye and the glass, or beyond also, if I made use of the refracting glass [L] Then looking stedfastly at the flame of this last candle, it was very plain to be perceived, that the flame thereof was encompassed with a stream of liquor, which seemed to issue out of the wick, and to ascend up in a continual current, or *jet d'eau,* to keep itself intire, and unmixt with the antient air, notwithstanding that it was a considerable way carried above the aforesaid flame"[7] Then he mentions "several turnings, whirlings, or vortices in the ambient air" familiar to all who ever have observed a burning candle in a schlieren apparatus In Fig 1, S may designate a region of streaks in homogeneous surroundings Owing to the gradient of refraction the bundle of rays R penetrating this inhomogeneity will be deflected more or less from the pupil of the eye E so that the streaks stand out more or less dark against the bright background The pupil of the eye plays here, in principle, the same role as the knife edge in the methods of Foucault and Toepler[4,8],


Fig 1 A reconstruction of Robert Hooke's schlieren set-up C₁ the first (illuminating) candle, L the lens, E the eye of the observer, C'₁ the image of C₁ produced by L, in reality at the pupil of E, C₂ the second candle, S a region of streaks above C₂, R a bundle of rays of light passing through S For clarity the distances of C₁ and E from L are represented as smaller than they may actually have been

* Address Institut fur Wissenschaftliche Mikroskopie der Universitat Tubingen, Hausserstrasse 11, D-74 Tubingen, Federal Republic of Germany

but at present schlieren systems with a circular cutoff instead of the knife edge are also used[3]

Hooke explained the operation of his method in almost the same way "The manifestation of this phoenomena [*sic*] was from differing refractions of the body of the jet d'eau from that of the ambient air for the flame of the first candle being but small, and placed at a considerable distance from the refracting, or reflecting glass, the smallest variation in the refraction of the medium between the first glass and the eye caused the darkness to intermix with the light, so to exhibit the appearance of the heterogeneous jet d'eau"[7]

These words show, too, that Hooke obviously realised at least one of the conditions mentioned by Mach[8] for ensuring the sensitivity of the schlieren method that is, a small light source The subsequent passage which states that the first candle is "placed at a considerable distance from the refracting, or reflecting glass" is, however, ambiguous It could simply refer to long focal distances, another condition of sensitivity mentioned by Mach[8] On the other hand, it could refer to the first condition and signify that the flame of the first candle is imaged on the pupil of the eye at a reduced scale (Fig 1) Since even a small candle flame has an area greater than that of the pupil, the area of its image may by these means be made comparable with that of the pupil, so that a minute difference of refraction at a certain region of the object causes at least partial non-coincidence of both areas and hence a darkening in the image of that region This seems, however, to be valid only for the lens, for in the case of the mirror this interpretation contradicts the passage cited above which says that the first candle should be placed "between the eye and the superficies of the reflecting glass"

After having submitted his account, Hooke "promised to exhibit at the next meeting, an experiment to shew a phaenomenon not unlike this, to be produced by several bodies dissolved in oil of vitriol"[7] On March 28 of the same year he performed an experiment of dissolving salnitre in common water Here, a stream is observed "composed of water and of the particles of nitre dissolved therein" which "was here descending, as in the former experiment a stream or fluid produced by a candle dissolved by the air ascended"[7] This seems to be the experiment promised by Hooke, but he may have been mistaken or changed his mind about the appropriate substances Later on he demonstrated experiments on mingling oil of vitriol and water, but here no observations of streaks are reported

Hooke mentioned his schlieren experiment once more in his Cutlerian Lecture entitled "Lampas", which was published in 1677, although so briefly that it is recognisable only by those familiar with it "This Figure and shape of the flame and vapours may be plainly seen by the help of a Metalline Concave placed at a certain distance and Position, and also by observing the shadow of the candle cast by the beams of the Sun upon a sheet of white Paper, or white Wall, but the way of a Concave *speculum* is incomparably beyond it, because it doth so very plainly shew the form and manner of the streams rising above "[9] The second, less sensitive procedure mentioned here is the same in principle as the shadowgraph method introduced into schlieren optics by Dvorak in 1880[3,10] The same effect can be observed when the sun is shining through blown window panes

Finally, Hooke repeated his experiment before the Royal Society on January 16, 1678 (or January 26, 1679, Gregorian calendar), and the short report ends "This was plainly seen by the president and divers others of the members present to their satisfaction"[7] At the same date Hooke records briefly in his diary "Shewn experiment of flame"[8]

At much the same time another schlieren experiment had been performed by Christian Huygens[11] He illuminated the back of a convex lens with the reflected light of a candle in a way similar to Hooke's method, observing the reflection in order to test the surface for defects of polish, as well as the glass for streaks These defects of polish are local irregularities in the surface which, analogous to streaks, deflect the light into another direction than their surroundings and can therefore be made visible in the same way by schlieren methods With lenses of great focal length Huygens even used a small telescope to observe the schlieren image, a fact Toepler emphasises as an advantage of his method compared with that of Foucault[4]

Huygens certainly developed his method without knowledge of Hooke's procedure, for if he had been acquainted with it, he would not have hesitated to repeat the experiment with the candle which is still today one of the most spectacular demonstrations in schlieren optics He seems to start from his thinking of the laws of image formation in terms of the "point de confusion maximum" (point of maximal blurring), by which he means simply the image point of an object If one observes a candle through a lens, the image of the candle becomes increasingly blurred as the eye moves back from the lens At the point mentioned above the blurring reaches a maximum because the whole aperture of the lens is filled with light and the image of the candle is lost As the distance of the eye from the lens increases, the image becomes clearer once more and finally, one is able to discern an inverted image of the candle Hooke's description of his method shows that he was familiar with this observation too

This concept has been used by Huygens in his *La Dioptrique*[12] published in 1653, but his schlieren method was evidently invented much later It was first published posthumously in 1703, but the editors of his *Oeuvres Complètes* fix it at 1685[11], 13 years after Hooke This date seems to be justified, for in a letter to his brother Constantyn who had often made telescope lenses with him, dated October 7, 1686, Christian Huygens described his method as if it were new and added the words "Je voudrois que vous fussiez icy pour estre present a cette epreuve"[13] (I wished you were here in order to be present at that test)

Huygens' method, though rarely mentioned in literature, has obviously not been completely forgotten by the experts, as has been the fate of Hooke's findings The well known glassmaker Pierre Louis Guinand, who collaborated later on with Fraunhofer, reported that he became acquainted with it in 1798 when he was visiting the opticians at Paris[14] It seems very probable that the news of Huygens' method reached Paris through the well known work *A compleat System of Opticks* by Robert Smith[15], first published in 1738 Huygens's treatise had originally been written in Dutch, but was later translated into Latin (by Hermann Boerhave, according to Abraham Gotthelf Kastner in the German translation of Smith's book) Smith certainly made Huygens's ideas better accessible by reporting them in English Since, however, the very skilled optician Mitouflet Thomin in Paris was obviously ignorant of these techniques in 1749[16], one may assume that it was the publication of the French translation of Smith's work in 1767[17] that changed the situation A connection between the knowledgeability of the opticians at Paris and Léon Foucault may thus not be completely excluded

The relatively detailed accounts of Hooke concerning streaks, as well as his schlieren set-up, are essential for interpreting the scanty and rare hints at microscopical methods related to schlieren techniques that have been dropped by Hooke and some other old microscopists Such investigations are now in progress

Possible power source of Seyfert galaxies and QSOs

J. G. Hills

Department of Astronomy, University of Michigan, Ann Arbor, Michigan 48104

The possible presence of massive black holes in the nuclei of galaxies has been suggested many times In addition, there is considerable observational evidence for high stellar densities in these nuclei I show that the tidal breakup of stars passing within the Roche limit of a black hole initiates a chain of events that may explain many of the observed principal characteristics of QSOs and the nuclei of Seyfert galaxies

STARS of mean density ρ are broken apart by the tidal force of a black hole of mass M if they pass within a distance

$$R_T \simeq (6M/\pi\rho)^{1/3} \tag{1}$$

of it They are physically absorbed by the black hole if they pass it within the gravitational radius,

$$R_G = 2GM/c^2 = 2\,95 \text{ km } (M/M_\odot) \tag{2}$$

R_T and R_T/R_G as functions of M are given in Table 1 I have assumed solar type stars in evaluating ρ in equation (1) For $M < 3 \times 10^8 M_\odot$, the tidal radius is greater than the gravitational radius so that stars are far more likely to be broken apart by the black hole than absorbed whole By the time the black hole has grown to the critical mass $M_c \simeq 3 \times 10^8 M_\odot$, it may have produced several times its own mass in gas, by breaking up stars This may be the source of the net outflow of gas observed in the nuclei of many galaxies

Capture of gas by the black hole

Much of the gas produced by tidal breakup is captured and subsequently accreted by the black hole The tidal breakup of a star requires energy which is ultimately supplied by a reduction in the kinetic energy of the star with respect to the black hole The energy required to break up a star of mass m and radius R is

$$E_b = \tfrac{3}{4}(Gm^2/R) \tag{3}$$

for a polytrope of index $n = 3$ The gas produced by the breakup of a solar type star is captured into a bound orbit by the black hole if the velocity of the star with respect to the black hole

before their encounter was less than 535 km s^{-1} Thus if the velocity dispersion of the stars in the nucleus of a galaxy is less than about 500 km s^{-1}, much of the gas produced by tidal breakup is captured and ultimately accreted by the black hole

For the larger black holes, which have $R_T \sim R_G$, emission of gravitational radiation may also be important in reducing the kinetic energy of the star with respect to the black hole[1], but I shall not consider this additional loss mechanism here

The gas produced by the breakup of a particular star may travel in a bound orbit to a large distance from the black hole, but eventually it must return to the original periastron distance of its stellar precursor The mean semi-major of the gas produced by the breakup of a solar type star by a black hole of mass M is

$$r = (2M/3m)R[1 - 2\langle V^2 \rangle R/3Gm]^{-1}$$
$$= 1\,5 \text{ pc } (M/10^8 M_\odot)[1 - \langle V^2 \rangle/(535 \text{ km s}^{-1})^2]^{-1} \tag{4}$$

where $\langle V^2 \rangle$ is the mean-squared velocity of the stars in the galactic nucleus before their encounter with the black hole Thus a $10^6 M_\odot$ black hole is surrounded by a massive gas cloud with a typical radius of 10^{-2} pc The dust in this cloud strongly absorbs the ultraviolet radiation emitted by the gas being accreted by the blackhole This may be responsible for the infrared emission of QSOs and Seyferts The ionised gas in this large cloud may in turn be responsible for the forbidden-line radiation from QSOs

Collisions among the gas clouds originating from the breakup of individual stars will release enormous amounts of energy High velocity collisions between gas clouds can explain several phenomena associated with QSOs (ref 2) The dissipation of energy from collisions reduces the effective semi-major axis of the gas until it is well within the Roche limit Ultimately the gas must be accreted by the black hole unless it is stopped by rotation Even if this occurs, the gyration radius of the gas must be much less than the Roche limit of the black hole unless the gas acquires additional angular momentum after the breakup of its stellar progenitors by interacting with the stars around the black hole If the angular momentum is sufficiently large that the gas settles into a disk spinning around the black hole, viscous forces eventually will allow most of this gas to be accreted by the black hole as in an X-ray binary[3,4] The accretion of gas by a massive black hole produces a large amount of ultraviolet radiation[4] which will tend to ionise the massive gas cloud around the black hole to produce the observed forbidden-line radiation and the cores of the permitted lines The Doppler broadening

Table 1 Breakup and accretion of stars by a black hole

M/M_O	R_T/R_O	R_T/R_G	L_E/L_O (Eddington Limit)	t_E (yr)	L/L_E ($\rho_s = 10^6 M_O$ pc^{-3})	t_D (yr)
10^1	4 31	$1\ 02\times10^5$	$3\ 2\times10^5$	$1\ 6\times10^9$	$1\ 5\times10^{-3}$	$1\ 8\times10^{11}$
10^2	9 28	$2\ 19\times10^4$	$3\ 2\times10^6$	$1\ 4\times10^9$	$3\ 2\times10^{-3}$	$8\ 4\times10^{10}$
10^3	20 0	$4\ 72\times10^3$	$3\ 2\times10^7$	$1\ 2\times10^9$	$7\ 0\times10^{-3}$	$3\ 9\times10^{10}$
10^4	43 1	$1\ 02\times10^3$	$3\ 2\times10^8$	$9\ 4\times10^8$	$1\ 5\times10^{-2}$	$1\ 8\times10^{10}$
10^5	92 8	$2\ 19\times10^2$	$3\ 2\times10^9$	$7\ 3\times10^8$	$3\ 2\times10^{-2}$	$7\ 9\times10^9$
10^6	200 0	$4\ 72\times10^1$	$3\ 2\times10^{10}$	$5\ 2\times10^8$	$7\ 0\times10^{-2}$	$3\ 3\times10^9$
10^7	431 0	$1\ 02\times10^1$	$3\ 2\times10^{11}$	$3\ 2\times10^8$	$1\ 5\times10^{-1}$	$1\ 2\times10^9$
10^8	928 0	2 19	$3\ 2\times10^{12}$	$1\ 1\times10^8$	$3\ 2\times10^{-1}$	$2\ 7\times10^8$
$3\ 2\times10^8$	1,374 0	1 00	$1\ 0\times10^{13}$	0	$4\ 8\times10^{-1}$	0

resulting from the rotation of the gaseous disk around the black hole and the large random velocities of dense colliding gas clouds near the black hole may be responsible for the large widths of the permitted emission lines in Seyferts and QSOs

Luminosity and total energy

It is evident that most of the mass acquired by a black hole less massive than $M = 3\times10^8 M_O$ is from the accretion of gas rather than of whole stars In this case the total energy released by this accretion is $E = 0\ 057\text{-}0\ 43 Mc^2$ depending on the angular momentum of the black hole[5] If $E = 0\ 2Mc^2$, the total energy released by the black hole by the time its mass reaches the critical value $M_c = 3\times10^8 M_O$ is $E_c = 1\ 1\times10^{62}$ erg $\equiv 9\times10^{20} L_O$ yr The maximum luminosity produced in the accretion of material by the black hole is given by the Eddington[6] limit,

$$L_E = 3\ 2\times10^4 L_O(M/M_O) \tag{5}$$

Thus the maximum possible luminosity produced by the accretion of gas by the black hole is $L = 10^{13} L_O$ which occurs when $M = M_c$ This is very near the peak observed luminosity of QSOs The total energy release could power a quasar at this luminosity for as long as 9×10^7 yr

If $E = 0\ 2Mc^2$, the rate of mass accretion by a black hole growing at the Eddington limit is

$$dM/dt_E = 1\ 1\times10^{-8}\ M_O\ \text{yr}^{-1}\ (M/M_O) \tag{6}$$

In this case, the time required for a black hole to grow from a mass M to $M_c = 3\times10^8 M_O$ is

$$t_E = 9\ 3\times10^7\ \ln(M_c/M)\,\text{yr} \tag{7}$$

Table 1 shows t_E and L_E as a function of M I assume that the luminosity of a QSO drops by orders of magnitude when its mass reaches $M = M_c$ at which point the stars are swallowed whole by the black hole rather than being broken apart tidally first

I note (Table 1) that a seed black hole growing at the Eddington rate takes about $1\ 6\times10^9$ yr to increase its mass from about $10 M_O$, a mass one may expect from stellar evolution, to $M_c = 3\times10^8 M_O$ So the observed number of QSOs in the Universe would decrease very rapidly after the Universe was more than $1\ 6\times10^9$ yr old If the Universe is presently $1\ 2\times10^{10}$ yr old, this critical time corresponds to $Z = 2\ 8$ in an Einstein–de Sitter universe This is consistent with the observations of Schmidt[7] that the density of QSOs in the Universe increases as $(1+Z)^6$ up to $Z \simeq 2\ 5$ and then it either remains constant or decreases for larger Z

Growth governed by stellar density

If the density of stars in the nucleus of a galaxy is not sufficiently large, this density rather than the Eddington limit governs the rate of growth and luminosity of the black hole Assuming

Newtonian mechanics, the rate at which gas is being produced by the breakup of stars passing within the Roche radius R_T of a black hole of mass M is

$$\frac{dM}{dt} = \rho_s\langle\sigma V\rangle$$

$$= 8\ 6\times10^{-16}\frac{M_O}{\text{yr}}\left[\frac{\rho_s}{M_O/\text{pc}^3}\right]\left[\frac{R_T}{R_O}\right]\left[\frac{M}{M_O}\right]\left[\frac{\text{km s}^{-1}}{\langle V^2\rangle^{1/2}}\right]$$

$$= 1\ 9\times10^{-16}\frac{M_O}{\text{yr}}\left[\frac{\rho_s}{M_O/\text{pc}^3}\right]\left[\frac{\text{g cm}^{-3}}{\rho}\right]^{1/3}\left[\frac{M}{M_O}\right]^{4/3}\times$$

$$\times\left[\frac{\text{km s}^{-1}}{\langle V^2\rangle^{1/2}}\right] \tag{8}$$

Here ρ_s is the stellar mass density in the vicinity of the black hole It is assumed that at very large distances from the black hole the stars have a Maxwellian distribution of velocities with an r m s velocity $\langle V^2\rangle^{1/2}$ In this derivation I have assumed that the mass and radius of a typical star broken apart by the black hole are much smaller than the mass and tidal radius of the black hole I have also made use of the fact that the escape velocity at a distance R_T from the black hole is very much greater than $\langle V^2\rangle^{1/2}$

If all the gas produced in the breakup of the stars is accreted by the black hole integrating equation (8) suggests that the time required for a black hole to grow from a mass M to a mass M_c is

$$t_D = 1\ 7\times10^{15}\,\text{yr}\left[\frac{M_O\,\text{pc}^{-3}}{\rho_s}\right]\left[\frac{M_O}{M}\right]^{1/3}\left[1-\left(\frac{M}{M_c}\right)^{1/3}\right]\times$$

$$\times\left[\frac{\langle V^2\rangle^{1/2}}{\text{km s}^{-1}}\right] \tag{9}$$

Here I have assumed solar type stars so that $\rho = 1\ 41$ g cm^{-3} Table 1 shows t_D as a function of M for a galactic nucleus in which $\rho_s = 10^6 M_O$ pc^{-3} and $\langle V^2\rangle^{1/2} = 225$ km s^{-1}, the observed velocity dispersion in the nucleus of M31 (ref 7) The table also gives the luminosity, L, in units of the Eddington luminosity, L_E Here I have used $L = 0\ 2\,(dM/dt)\,c^2$ I note that at a fixed M, $(t_D)^{-1} \propto L \propto \rho_s/\langle V^2\rangle^{1/2}$

Thus simple scaling gives L and t_D for a galactic nucleus with any other value of ρ_s and $\langle V^2\rangle^{1/2}$ It is not likely that $\langle V^2\rangle^{1/2}$ differs very much from one nucleus to another, but there are sizable differences in ρ_s Assuming $M/L = 10 M_O/L_O$, the data of Kinman[8] indicate that $\rho_s \simeq 10^5 M_O$ pc^{-3} within 1 pc of the nucleus of M31 For the nucleus of our Galaxy infrared observations[9] indicate that $\rho_s \simeq 7\times10^6 M_O$ pc^{-3} within 0 5 pc of its centre Schwarzschild[10] finds indirect evidence of $\rho_s = 2\ 2\times10^8 M_O$ pc^{-1} within 3 5 pc of the nucleus of

the Seyfert galaxy NGC4151 For a black hole to have had enough time to grow to $M_c = 3 \times 10^8 M_\odot$ within the age of the Universe (which I assume to be $1\,2 \times 10^{10}$ yr), the initial mass of the black hole had to exceed $M_i \simeq 10^7 M_\odot$ in the nucleus of M31, $M_i \sim 10^2 M_\odot$ in the nucleus of our Galaxy, and $M_i \lesssim 1 M_\odot$ in the nucleus of NGC4151 The very low value of M_i for NGC4151 suggests that Schwarzschild's estimate for ρ_s may be somewhat large From the values of L/L_E in Table 1, a black hole in the nucleus of M31 could never break up stars fast enough to allow it to radiate at the Eddington limit In our Galaxy a black hole would radiate at the Eddington limit when its mass is equal or greater than $M_E = 10^7 M_\odot$, for NGC4151 this occurs when $M_E = 10^2 M_\odot$ When $M > M_E$ the breakup of stars by the black hole produces gas faster than the Eddington limit allows it to be accreted by the black hole In these cases, we may expect the surplus gas to be driven out of the nucleus by radiation pressure Such outpouring of gas is observed in several Seyferts This mass loss can be prodigious If $\rho_s = 10^7 M_\odot$ pc^{-3}, the mass loss rate approaches $12\,5$ $M_\odot$ yr^{-1} as M approaches M_c The mass loss rate as well as the luminosity would then drop effectively to zero for $M > M_c$

If present ideas on the evolution of massive upper main sequence stars are correct, we may reasonably expect black holes with masses of about $M_i = 10 M_\odot$ to form in almost every galactic nucleus Such black holes would have had sufficient time in our Universe to grow to $M_c = 3 \times 10^8 M_\odot$ if the stellar density in the galactic nucleus exceeds $(\rho_s)_0 = 1\,5 \times 10^7 M_\odot$ pc^{-3} (Table 1) This watershed density is very sharply defined If ρ_s is even 2–3 times less dense than this, the minimum mass of a seed black hole which has sufficient time to grow to M_c in the age of the Universe increases sharply to 10^2–$10^3 M_\odot$ which is much greater than the masses of black holes formed by normal stellar evolution If $\rho_s > 2$–3 $(\rho_s)_0$, almost any black hole has time to grow to M_c Thus any QSO or Seyfert nuclei present today are likely to have a stellar density of about $1\,5 \times 10^7 M_\odot$ pc^{-3} or slightly greater At this density the black hole radiates at the Eddington limit for $M > M_E = 10^5 M_\odot$ If $\rho_s \geq 10^8$–$10^9 M_\odot$ pc^{-3} any black hole with $M > 10 M_\odot$ would grow at the rate governed by the Eddington limit These black holes would have reached $M = M_c$ at about $Z = 2\,8$ in the observable Universe Thus there should be a maximum in QSO activity at this epoch followed by a rapid decline for lower values of Z This is consistent with observations[7]

Two refinements may increase somewhat the rate at which stars are swallowed by the black hole One complication is the possible formation of a high density stellar cusp around a black hole embedded in a dense stellar nucleus[11] Another is the shrinking of the entire stellar nucleus as its stars are captured by the black hole How this arises can be seen by considering the effect of these captures on a typical star in the nucleus Some of the stars captured by the black hole are in orbits in which, on the average, they are further from the black hole than the test star At some point in time each of these stars crosses inside the orbit of the test star never to return Thus, as these stars are accreted by the black hole, the test star and the other remaining stars in the nucleus feel a progressively increasing gravitational potential To satisfy the virial theorem, the velocity dispersion of the stars in the nucleus must increase This added kinetic energy is supplied by a net shrinking of the effective radius, R_N, of the galactic nucleus The increase in the velocity dispersion of the stars in the nucleus would by itself decrease the rate of accretion by the black hole, but this is more than compensated by the increased stellar density in the nucleus I note that $\langle V^2 \rangle \propto R_N^{-1}$ while $\rho_s \propto R_N^{-3}$ (actually, $\rho_s \simeq R_N^{-2}$ when stars accreted by the black hole are considered) From equation (8), this results in a net increase in the rate of accretion by the black hole compared to the case where we ignore both the increased density and the increased velocity dispersion in the galactic nucleus This effect can only become important as the mass of the black hole approaches that of the galactic nucleus or $M \sim 10^8 M_\odot$

Orbit diffusion and relaxation time

In the previous section, particularly in the derivation of equation (8), I made the implicit assumption that the rate of orbit diffusion resulting from the random gravitational encounters between stars is sufficiently fast that at any given time the number of stars with orbits that pass within the Roche radius, R_T of the black hole is nearly the same as it would be if there was no breakup of these stars This is true as long as the total mass M_n of the stars in the galactic nucleus is large compared to the mass M of the black hole In the absence of orbit diffusion, the velocity distribution of the stars at a given point in the nucleus would be isotropic (if the stellar distribution is relaxed) except for those velocity directions corresponding to orbits which cross R_T On average, the fraction, F_v, of the velocity directions occupied by these orbits is the fraction of all stars in the nucleus that have orbits which intersect R_T Thus as long as $F_v \lesssim 1$, a very small amount of velocity randomisation is sufficient to fill in these small holes in the otherwise isotropic velocity distribution and consequently to repopulate the orbits that cross R_T In other words the time necessary to repopulate these orbits is very small compared to the relaxation time[12],

$$t_R = V^3/4\pi G^2 m^2 n \ln N \qquad (10)$$

which is the time necessary to completely rerandomise the velocities In the typical galactic nucleus of interest, $V = 225$ km s^{-1}, $n = 10^7$ stars pc^{-3}, $m = 1 M_\odot$, $M_n = 10^8 M_\odot$, and $N = M_n/m = 10^8$ In this case $t_R = 3 \times 10^8$ yr

The rate of orbit diffusion is sufficiently large to result in there being no significant depletion of the stars with orbits that cross R_T as long as the characteristic time for the consumption of all the stars in the galactic nucleus by the black hole is greater than the relaxation time, that is, the diffusion rate is sufficient as long as $M_n/|dM_n/dt| > t_r$ If $M_n \sim 10^8 M_\odot$, this condition is satisfied until the mass of the black hole has grown to $M \sim M_c$ Thus the assumption of an adequate rate of orbit diffusion implicit in the previous section is valid

A massive black hole at the galactic centre?

Any such object would have to be very modest to produce no more than the observed nonstellar radiation emitted from the nucleus If gas accretion by this object produces all the ionising radiation required to maintain the H II region at the galactic centre, the luminosity of this radiation is $L_i = 1\,9 \times 10^8 L_\odot$ (ref 13) if the energy per photon is 2 rydberg From Table 1, with $\rho_s = 7 \times 10^6$ $M_\odot$ pc^{-3}, this requires a black hole mass $M \simeq 4 \times 10^4 M_\odot$ Equation (3) requires that the radius of the cloud of gas and dust produced by the breakup of stars by a black hole of this mass be $\langle r \rangle \simeq 10^{-3}$ pc This is at least consistent with the observed "point" infrared source at the galactic centre which has a radius of less than $0\,1$ pc and a luminosity of 3×10^5 $L_\odot$ (ref 8) $M \simeq 4 \times 10^4$ $M_\odot$ is likely to be a firm upper limit on M The ionisation could be due to something else If M is this large, it would only take another $1\,5 \times 10^9$ yr to grow to M_c It is unlikely (but of course not impossible) that we would catch the black hole just at this crucial stage in its growth A more troublesome point is the fact that the initial mass of this object had to be about $10^2 M_\odot$ to have reached $M = 4 \times 10^4$ by the present epoch This initial mass seems rather large from the standpoint of stellar evolution If the luminosity of the infrared source results from the accretion of stars broken up by the central black hole, its mass must be at least $M \simeq 3 \times 10^2 M_\odot$ This is probably the minimum mass of the central black hole The initial mass of this black hole need only have been slightly greater than $10 M_\odot$ to have allowed it to grow to $3 \times 10^2 M_\odot$ in $1\,2 \times 10^{10}$ yr It will take another 10^{10} yr for such a black hole to grow to $M = M_c$

An examination of the concentrations of the incompatible elements in tholeiites from the Kolbeinsey Ridge indicates that plume magmas have probably not overflowed into that area from Iceland or Jan Mayen Island The results also show that the chemistry of plume magmas may be intimately related to regional geochemical patterns, and it is possible that Iceland represents a 'weak spot', or decompression focus, which causes complex flow patterns within and from the asthenosphere

WE present here petrological data on dredge samples recovered from the mid-oceanic Kolbeinsey Ridge north of Iceland Most of the materials described were recovered during two cruises in 1972–73 in the North Atlantic

Iceland and Jan Mayen Island represent subaerial expressions of recent volcanism associated with the Iceland Plateau and Kolbeinsey Ridge Iceland consists of an extensive, largely tholeiitic, flood-basalt plateau built up in about the last 30 Myr and cut by three neovolcanic zones containing tholeiitic, alkalic and other basalt types[1-3] Its great volumes of lava, their high discharge rates and relatively high contents of K, Ti, P, rare earth elements (REE), $^{87}Sr/^{86}Sr$ and so on have been considered expressions of a hot, rising mantle plume[2,4-6]

The older Faeroes and East Greenland basalts also have K, P, and Ti values comparable to those found in Iceland[7], and this may be[8] the result of plume activity in the early Tertiary

Jan Mayen Island consists of ankaramites, alkali basalts and their differentiates together with their explosive equivalents, tholeiitic flows are unknown Subaerial material only dates back to 0 5 Myr BP but construction of the island's base could be assigned to the mid-Tertiary or early Pleistocene[9,10] A plume origin has also been proposed for Jan Mayen Island[11] The two islands lie at the limits of the Iceland Plateau, a generally smooth (presumably basaltic) platform at a depth of less than 1 km (refs 12 and 13) Transecting this plateau is the Kolbeinsey Ridge, an accretion centre erupting basalts at its axis and with minimal sedimentary cover[13-15] Possible extensions of recent Icelandic and Jan Mayen plume activity may thus be sought along the Kolbeinsey Ridge

The Kolbeinsey Ridge (66° 30'N–71° 50'N) extends, with a generally NNE trend, for a distance of approximately 550 km from Iceland to the Jan Mayen Fracture Zone and cuts the Icelandic Plateau at depths of less than 1,300 m (Fig 1) The ridge begins as a subdued N–S trending rift valley and corresponding magnetic anomaly which gradually develops on the outer northern Icelandic Shelf The shallow ridge axis surfaces at the islet of Kolbeinsey, 67° 08'N (ref 16) North of Kolbeinsey Islet as far as the Spar Fracture Zone (69°N) the ridge strikes N 28°E and has a step-like structure lacking a central rift valley,

it is similar in morphology to the northern Reykjanes Ridge In addition, this ridge segment also resembles the Reykjanes Ridge in spreading rate, free-air and Bouguer anomalies, and magnetic anomalies[14] Remanent magnetisation values on drilled cores from pillow basalts from this ridge segment obtained by our shipboard spinner magnetometer averaged 0 05 e m u , similar to the average values found for pillow basalts on the Reykjanes Ridge[17] Furthermore, thin sections show phenocryst assemblages of plagioclase–olivine–clinopyroxene (dredges 7–72, 9–72, see Table 1) which are also characteristic for pillow basalts from the Reykjanes Ridge[4,18] Thus, the conclusion[14] that this segment of the Kolbeinsey Ridge seems to be the northern counterpart of the Reykjanes Ridge is probably correct

North of the Spar Fracture Zone, the Kolbeinsey Ridge is offset about 30 km to the east and then takes on the classical mid-oceanic ridge structure with a well developed rift valley trending N 14°E An unnamed fracture zone at 70° 52'N delimits the southern side of Eggvin Bank, a broad seamount transected by the ridge axis From the top of Eggvin Bank, only 50 m below the waves, the ridge gradually deepens towards the Jan Mayen Fracture Zone which reaches depths greater than 2 km

Chemistry of Kolbeinsey Ridge tholeiites

Table 2 presents the concentrations of K_2O, TiO_2, P_2O_5 and Sr in tholeiites from the Kolbeinsey Ridge, these have been plotted against the morphology of the ridge axis (Fig 1) Tholeiites from the ridge axis between 67° and 70° 35'N have similar low contents of the incompatible elements, low levels of K_2O, TiO_2, P_2O_5 and Sr characterise fresh mid-oceanic ridge tholeiites[19-21] In detail, the levels of K_2O, P_2O_5, Sr, and to a lesser extent TiO_2, are generally lower than oceanic ridge tholeiites south of the Charlie Gibbs Fracture Zone[20], and are more comparable to contents of the central and southern Reykjanes Ridge[4,18,22]

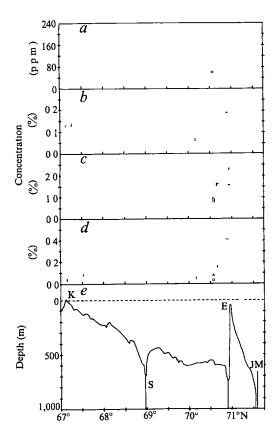
Eggvin Bank also consists of tholeiitic basalts but their elemental concentrations deviate sharply from the 'background level' determined for the ridge to the south Figure 1 shows that the concentrations of K_2O, TiO_2, P_2O_5 and Sr rise to a maximum at the upper parts of Eggvin Bank This peak in no way corresponds to the presence of highly evolved or fractionated basalts the $FeO*/MgO$ ratio of Eggvin Bank tholeiites is comparable with the ratio for tholeiites from the adjacent ocean floor to the south Moreover, fractional crystallisation would lead to a similar passive concentration of elements such as K and P which enter early mineral phases in negligible amounts In fact, K_2O concentrations are increased by a factor of seven over ridge values whereas P_2O_5 is only increased twofold The concentration of alkali and volatile elements within a high-level magma chamber[23] of Eggvin Bank is a possibility Alternatively, the lower TiO_2/P_2O_5 ratio of these summit tholeiites


Fig 1 Geochemical (a-d) and topographic (e) profiles along the Kolbemsey Ridge Concentrations of fresh tholeiites a, Sr, b, P₂O₅, c, TiO₂ d, K₂O e K, Kolbemsey Islet[16-21], E, Eggvin Bank, S, Spar Fracture Zone, JM, Jan Mayen Fracture Zone

compared with the adjacent ocean floor tholeiites may indicate a deeper origin for the Eggvin Bank basalts[24]

Interesting comparisons exist between Eggvin Bank and Iceland they are both elevated topographic features, partly bounded by fracture zones and cut by an accretion axis, and significant scatter is found in the concentrations of their incompatible elements

Tholeiites on the southern and northern flanks of Eggvin Bank show concentrations of incompatible elements which are

intermediate between those of the ridge axis and the summit of the seamount The decrease in the TiO₂/P₂O₅ ratio is also apparent in these intermediate samples We have only one sample (1351-1) from the northern flank of Eggvin Bank, recovered from a depth of 400-650 m at the ridge axis It shows no sign of approaching a more alkalic province although true alkali basalts have been recovered from the walls of the Jan Mayen Fracture Zone slightly to the north (unpublished data) It seems that this sample marks a return to ocean floor tholeiite chemistry Schilling[25] has reported, however, a normalised La/Sm ratio greater than 1 0 for a ridge sample from a deeper dredge only 15′ of latitude south of the Jan Mayen Fracture Zone Certainly, our samples do not provide evidence for any southward plume overflow from the Jan Mayen province extending to our most northerly sample, about 30′ of latitude south of the Jan Mayen Fracture Zone Three samples in dredge 1350-4 are also available from just to the south of the fracture zone at 70° 52′N They were recovered from the flank of the ridge axis and exhibit elevated concentrations of K₂O (0 15 to 0 20%) These slightly higher K₂O concentrations could reflect limited degrees of low temperature, seawater alteration and/or more potassic flank volcanism

In conclusion, the chemistry of the most southerly samples recovered from the Kolbemsey Ridge show no indication of approaching the postulated Icelandic mantle plume, the most northerly samples show no chemical similarities to samples from the highly alkalic Jan Mayen province Kolbemsey Ridge crest tholeiites, with the exception of those from Eggvin Bank, show very low concentrations of incompatible elements, reminiscent of the central and southern Reykjanes Ridge Eggvin Bank is considered to be the summit of a tholeiitic seamount sequence with enhanced contents of K₂O, TiO₂, P₂O₅ and Sr

Compositional gradient

We have assembled concentrations of K₂O for tholeiites from the Charlie Gibbs Fracture Zone at about 52° 46′N (Fig 2) through the presumed Iceland plume and along the Kolbemsey Ridge to the Jan Mayen Fracture Zone at about 71° 50′N, a distance of about 2,200 km There is a certain degree of symmetry north and south of Iceland both in the elevation of the ridge axis and also in its structural, geophysical and petrographic character Large sections of this geochemical profile remain unsampled, though some of the critical sections are reasonably well described With the exception of the samples recovered from Eggvin Bank and the Minia Seamount just east of the ridge

Table 1 Dredge stations, depth of recovery and rock description

Dredge no	Latitude and longitude	Depth (m)	Locality	Rock description
D7-72	67° 32 3′N 18° 31 2′W	445-467	Ridge crest	Pillow basalts 10-20% vesicles (≤ 1 5 cm across) 5-10% plagioclase phenocrysts (≤ 3 mm across)+smaller clinopyroxene and olivine crystals
D9-72	67° 58 5′N 18° 23 6′W	576-622	Ridge crest	Devitrified vesicular basalt, 15 % microphenocrysts of plagioclase+ olivine+clinopyroxene

axis, and D1350-4 from the ridge flank, all materials are from the ridge axis

All samples chosen for study were fresh Thin sections indicated that alteration was limited to slight discoloration of plagioclase and olivine phenocrysts, grains of chlorite, iddingsite and clay minerals were not observed Whole rock water contents did not exceed 0 7% Zonal variation in the concentrations of K_2O was observed in several basalt pillows For example, samples from D30–73 show their highest K_2O concentrations in the intermediate variolitic zone (0 078–0 079%), compared with the glassy margins (0 036–0 044%) and cores (0 027%)

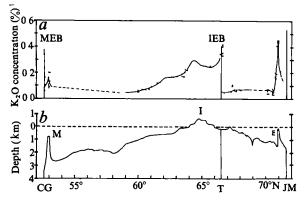
There is some correlation between the topographic profile and the K_2O concentrations in the tholeiites Three main divisions of the K_2O profile may be distinguished First, the great expanse of ocean floor, about 55% of the profile, where K_2O values range from about 0.03 to 0 11% K_2O, second, the Icelandic geochemical anomaly, where the uncertain line of best fit rises to a maximum of about 0 29%, and where the scatter of potash concentrations is at a maximum The seamounts of Minia and Eggvin both at the extreme limits of this profile and close to major fracture zones also represent scattered high-concentration potash zones, although much narrower than Iceland Lastly, there is a mixed belt for the northern Reykjanes Ridge, where K_2O concentrations rise from oceanic to Icelandic levels There is some indication of a 'plateau' in the trend, corresponding to the southern insular shelf of Iceland Certainly, the K_2O contents of tholeiites reported from this shelf show no clear increase towards Iceland, although extending over 20' of latitude[26]. From the available evidence it can be seen that an extensive mixed zone is not present (Fig 2) on the northern shelf of Iceland This shelf is cut by the Tjornes Fracture Zone which offsets the spreading axis by about 100 km (ref 27) and may act as a barrier to any northward flow of the asthenosphere[25]


Fig. 2 K_2O concentration (*a*) and topographic (*b*) profiles along the mid-oceanic ridge between Charlie Gibbs (CG) and Jan Mayen (JM) Fracture Zones *a*, K_2O contents from fresh tholeiites[4,16,18,21,22,26,36], Major element boundary (MEB) from Campsie *et al*[18] and incompatible element boundary (IEB) from both Schilling *et al*[25] and this study *b*, M, Minia Seamount, E, Eggvin Bank, I, Iceland, T, Tjornes Fracture Zone

Of particular interest is the fact that the low K concentrations of the ocean floor tholeiites to the north and south of Iceland are shared by Iceland 'plume' theoliites The average K_2O concentrations of Icelandic tholeiites, both from the Tertiary plateau and the neovolcanic zones, are about 0 25% (unpublished compilation), and although this value is higher than that of the adjacent ridge tholeiites, it lies within the worldwide range of K_2O concentrations for fresh, ocean ridge tholeiites[20,21]

In contrast to Iceland and its environs, K_2O concentrations for the Galapagos plume tholeiites average about 0 36%, and the surrounding ocean floor tholeiites average close to 0 14% (refs 28 and 29) Thus, K_2O concentrations for tholeiites of the Icelandic region, regardless of their genesis, are about 70% of those for tholeiites of the Galapagos plume and its environs It follows that the geochemistry of plume magmas is to some extent integrated into the geochemical pattern of a broad region, and does not simply represent an independent magma type derived from independent deeper regions of the mantle, as implied by Morgan[6] Perhaps a fairly constant factor, additive or multiplied, will convert the K_2O concentrations of the plume to normal regional concentrations

Relationship between the plume and surrounding crust

There is one possibility whereby the Iceland 'plume' may be interrelated with the surrounding ocean floor The Iceland area may have begun at a 'weak spot' rather than at a 'hot spot' Such 'weak spots' may be located close to triple junctions or perhaps at the intersection of spreading axes and pre-existing tectonic lineaments, such as that delineated by the trend of the Faeroe–Iceland–Greenland ridge

Localised decompression would lead to more extensive melting and increased basaltic discharge Basalts generated at this focus of decompression would be equilibrated at shallower levels than normal, explaining the generally higher FeO*/MgO ratios of the basalts and also their lower eruptive temperatures[30] Further supplies of basaltic material would be sucked into this lower pressure region through the low velocity zone, preferentially bringing the more mobile incompatible elements with them[18] This transfer of material may lead to subsidence of the oceanic crust There may be little or no basalt replenishment because some fracture zones in this region may mark deep barriers to asthenospheric flow Therefore, any basalts generated in the regions of greatest subsidence will have low concentrations of incompatible elements and higher concentrations of refractory MgO, giving lower FeO*/MgO values The amounts of K, P, and so on transferred to the decompression zone may depend on the regional geochemical levels, and on the rate and degree of flow Excess volumes of basalts may be discharged away from Iceland at shallow crustal levels and may be mixed with normal oceanic tholeiites within elongated magma chambers[4] The available evidence suggests that while the Iceland landmass is rising[3], the seafloor to the north has subsided[31-34]

The cruises on which we collected our samples were a cooperative effort between the Ocean Study Group, the Mineralogical and Zoological museums, Copenhagen, the Museum of

Natural History, Reykjavik, and the US Naval Oceanographic Office We thank Professor A Noe-Nygaard, and N Hald of the Mineralogical Museum, Copenhagen, G L Johnson of USNO, and the officers and crew of the USNS Lynch for their support Further, we thank Dr A Sharaskin of the Vernadskiy Institute, Moscow and the staff of the Soviet R V Akademik Kurchatov for providing some of the samples Finally we express our appreciation to Erik Larsen and the Laboratory for Electrophysics, Technical University of Denmark, Lyngby for the design and construction of the shipboard magnetometer

Some evidence of chronology and palaeoecology of Sterkfontein, Swartkrans and Kromdraai from the fossil Bovidae

E. S. Vrba

Transvaal Museum, PO Box 413, Pretoria, South Africa

Bovid fossil remains suggest a tentative chronology for the seven cave assemblages, from Sterkfontein, Swartkrans and Kromdraai, from which they are derived They also suggest that, during the almost 2 Myr of South African hominid and faunal Pleistocene history encompassed by this succession of assemblages, certain changes in vegetation cover and cave accumulation patterns may have occurred in the Sterkfontein Valley

THE cranial bovid material derives from the following subdivisions, or site units, of Sterkfontein, Swartkrans and Kromdraai, all situated in the Sterkfontein Valley (see Fig 37 in ref 1) near Krugersdorp, South Africa STS, Sterkfontein type locality, SE, West Pit of the Sterkfontein extension locality, D16, Sterkfontein rubble dump 16 , SKa, Swartkrans assemblage from primary[2] (formerly pink[1]) breccia, SKb, Swartkrans assemblage from (1) secondary[2] (formerly brown[1]) breccia, and from (2) fills of channels forming at a relatively late stage through both primary and secondary breccias, KA, Kromdraai faunal site, KB, Kromdraai australopithecine site A brief summary of some currently available ideas on the hominid and cultural associations of these site units is shown in Fig 2 and the bovid species identified at these site units are shown in Table 1

Chronology

Much of the bovid material was found to correspond taxonomically to a greater or lesser extent with material from other sites (discussed in ref 3) Figure 1 shows the temporal sequence of the site units, and its possible correspondence with other African sites and with the absolute time scale, as suggested by these bovid data The most notable changes from previously accepted

chronological evaluations are as follows It is clear that Swartkrans fossils include a substantial component that may be considerably later than the assemblage associated with australopithecines, and that Swartkrans cannot, as in the past, be considered as one unit in studies of this kind The present bovid data also suggest that KA, KB and SE should not be included in the Swartkrans span, as has been variously done in the past, but that they may belong to the succeeding Cornelia span Note that the present study was uninformative as to how far back in time STS and Makapansgat Limeworks may have extended[3] These positions in Fig 1 represent upper limits only

Vegetation cover and climate

It is assumed here, as previously[8], that the Alcelaphini and Antilopini are as a whole, among bovid tribes, indicative of open plains and grassland environments The validity of such an assumption in this particular study, especially its application to unusual fossil forms like *Makapania*, has been discussed[3] The fact that the percentages in Fig 2 never fall below 51 % seems to indicate that the past environments, corresponding to these assemblages, as a group fall distinctly into the vegetationally more 'open' part of the spectrum of known habitats Seen from a broad perspective, therefore, these bovid data may corroborate the view[11] that each of the breccias in question basically represents colluvial sediments compatible only with an incomplete mat of vegetation Figure 2, however, suggests differences within this overall environmental characterisation The most notable difference lies between STS and the group formed by SKa, KA, SE and, less certainly, KB (the difference in percentages of STS and SKa is statistically significant[3]) It cannot be suggested that the smooth curve in Fig 2 mirrors an equally smooth, simple environmental trend during the Pleistocene in the Sterkfontein Valley Some quite substantial fluctuations may not be included in this small sampling of the whole period Figure 2, however, may broadly represent an overall trend in the area, and probably further afield It is likely that during most of the Middle Pleisto-

Minimum numbers of individuals, rather than the basic fossil numbers available in ref 3, are used This is in accordance with general practice in work on other Transvaal cave fauna (see also ref 4)

cene an open grassland environment predominated The onset of this open phase (in the broad sense and allowing for oscillations) succeeded a period of greater bush cover, although open country had also been prevalent during this period, as represented by STS and probably the Makapansgat Limeworks It has been mentioned previously[8] that either rainfall and/or temperature changes are likely to be responsible for vegetation cover changes such as that inferred between STS and succeeding Sterkfontein Valley phases, and that an explanation of the present bovid data invoking rainfall even minimally would seem to contradict Brain's findings that a general increase in rainfall, with minor fluctuations, occurred in the Sterkfontein Valley from the time of STS onwards

There is agreement from several sources[12,13] that a general faunal change took place in South Africa between STS and SKa times The bovid data suggest that an environmental change may have been responsible for the faunal change, at least in the Sterkfontein Valley It is thus not entirely idle speculation to consider whether the change from gracile australopithecines at STS and Makapansgat Limeworks to robust forms at SKa and KB may be environmentally correlated Published opinions on fossil hominid taxonomy range from those that place all Transvaal australopithecines into one species, possibly in chronosubspecies[14], to those that see them in separate species[15] or separate genera[16] If the latter view were taken one could note

that the basic premises of Robinson's[16] dietary hypothesis would fit an open grassland–robust correlation very well, although the last step (based on ref 1) of his argument would not, that is, seeing the 'crushing, grinding' robust vegetarian in a (slightly) wetter and more luxuriant environment than the gracile omnivore If one views the SKa and KB australopithecines as differently adapted to their gracile counterparts, perhaps one should consider whether their musculature was so massive and, the molars proportionally so large, because their 'vegetables' were of the tough grassland type The long-adapted Phase 1 hominid, or 'small object' vegetarian of Jolly's 'seed-eaters' hypothesis[17] fits well in this respect Of course, if these robust and gracile forms were considered to be similarly adapted[14], with the often cited skull and dentition differences merely a consequence of overall size difference, the only admissible correlation would be between vegetationally more open (and drier and/or colder) environments and larger body size

Is it a coincidence that an East African proliferation of bovids adapted to open country, apparently occurring during or above member G at Omo (A W Gentry, unpublished) and in the *M andrewsi* zone at East Rudolf (J M Harris, unpublished), seems to coincide temporally with the analogous South African development? It could be possible that such a change in faunal tribal representation, mirroring a change in environmental exploitation, marked the boundary between a Sterkfontein span (or similar term) and a succeeding span not only in the Sterkfontein Valley, but elsewhere in Africa as well

Possible accumulation patterns

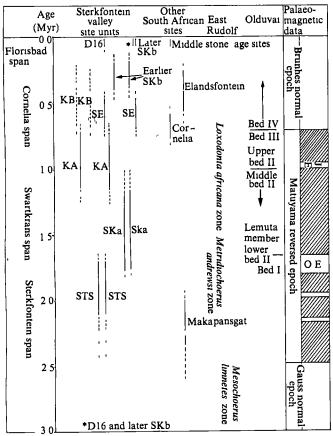
Some tentative suggestions as to the possible predominant causes of accumulation of these bovid assemblages are shown in Fig 3. To evaluate such aspects in this particular case, where only adult-juvenile and weight data of bovids from a series of cave accumulations are available, the following model was set up
Stage 1 bovids are killed by carnivore or hominid predators, (hominid hunters are included as a subset of the set of predators) in the vicinity of the cave, or die a natural death in or near the cave
Stage 2 remains of dead animals are brought into the cave eventually to constitute one or the other of the following
(a) Primary assemblage brought into the cave, which serves as a lair or shelter, by the primary predator(s), unlikely to contain a low percentage of juveniles, and if one predatory pattern predominates, most individuals should fall into a restricted body weight range
(b) Secondary assemblage brought into the cave by scavengers (for example, hyaena, hominid) and/or collectors (for example, porcupine, hominid), likely to contain a low percentage of juveniles, and the body weight distribution is likely to have a high variance
A fuller discussion of this suggested scheme, and of the validity of the implied characteristics of primary and secondary assemblages, is contained in ref 3 Most of the data in Fig 3 do not lend themselves to a statistical approach, and *what follows is a number of suggestions as to possible dominant accumulation patterns*
Juveniles of the smaller species are often eaten totally, or almost totally, by predators[18] and consequently have less chance of being preserved in fossil accumulations One can therefore expect fossil juvenile-adult ratios to be heavily biased towards adults With this consideration in mind juvenile percentages in STS, KA and D16 particularly, and in SKa, KB and SKb (Fig 3a), seem high in comparison with those recorded in live populations[19,20,21] In fact it looks as if juveniles might have been selected in preference to adults in these cases, and it is likely that they represent primary, or predominantly primary assemblages SE clearly differs from the other site units in this respect
STS. The most frequently occurring species are of medium to large size—weight class I is entirely absent The exceptionally high average weight (Fig 3c) indicates predators that were


Fig 1 The bovid data suggest chronological placement of the Sterkfontein Valley site units somewhere along the vertical lines drawn Palaeomagnetic and Olduvai data approximated from ref 5, East Rudolf faunal zones from refs 6 and 7 JE, Jaramillo Event, OE, Olduvai Event

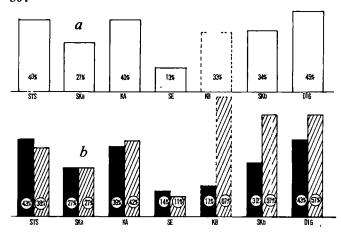
specialised on large prey It cannot be ruled out that *Australopithecus* contributed in the role of scavenger, but his main 'contribution' is likely to have been as carnivore prey STS carnivore remains include *Megantereon*, a true sabre-tooth cat, *Dinofelis*, a false sabre-tooth cat, and a leopard[22,23] As individuals of the size preferred as prey by modern leopards[18] are in the minority, it seems likely that the major predators were the sabre-tooths Ewer[24] has pointed out that, as a result of highly efficient carnassial shear, these carnivores were well adapted to the slicing of meat The premolars, however, were so reduced that the animals could only have crushed the smaller bones, leaving the niche for bone-crushing specialists, like hyaenids, wide open Brain[25] further elaborated on this idea "Regrettably little is known about the behaviour of South


African sabre-tooths and it is uncertain whether they were dominant to the associated hyaenas or whether they were forced to retreat with their prey into the seclusion of caves or trees"[17] During much of the accumulation period the STS cave may have been such a sabre-tooth lair Whole kills, or parts of larger kills may have been brought to the cave for peaceful consumption by the predator and its brood

SKa and KA. Brain[25] has given convincing reasons why the predominant contribution to the SKa assemblage should have come from leopards In comparing remains from KA and KB (C K Brain, personal communication) he has noted the following Although the more complete specimens in the former assemblage suggest that KA may have been a carnivore lair, the extremely fragmented KB bone remains may represent food remains of hominid hunters The bovid assemblages from SKa and KA seem to support these ideas In both cases the majority of individuals include high percentages of juveniles and fall into a restricted medium weight range, suggesting dominant predators of a somewhat smaller prey adaptation than those at STS (in the case of KA possibly the large lion-like felid present in that assemblage) As at STS the percentages of juveniles do not increase in the larger weight categories (Fig 3b) In both cases adult bovids in the largest weight class, as well as sabre-tooth remains, are present, suggesting that these predators may have played a secondary role

KB, SKb, D16. The last three site units in Fig 3 have several features in common Like the three earlier carnivore assemblages they have high overall juvenile percentages, although they diverge sharply from STS, SKa and KA in Fig 3b and c All three later assemblages are strongly dominated by species of low weight In each case the few large-sized individuals include a distinctly higher percentage of juveniles than do the lower weight classes The pattern is again strongly suggestive of predation, this time by a predator specialised on small prey The three site units have more in common They have been placed last in the chronological sequence on taxonomic grounds The presence of both *Homo* and stone tools is either known, or inferred for reasons independent of their similarity in Fig 3, in all three site units The obvious conclusion is that KB, SKb and D16 each represent (predominantly, if not entirely) the food remains of hominid hunters Note that while scavenging probably did play a part, Fig 3a–c are unanimous in stressing an over-riding hunting pattern

SE. The presence at this site unit of numerous stone tools suggests that the Sterkfontein cave during SE times may have been an occupation site of hominids Yet the pattern at SE (Fig 3) is quite different from those presented by the inferred hominid hunting remains from KB, SKb and D16 In fact, its markedly low juvenile percentage and the broad, platykurtic distribution of only 23 individuals throughout all weight classes, suggest that SE represents the only markedly non-primary

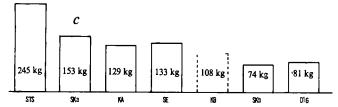
Fig 2 The percentage constituted by the added minimum numbers of alcelaphine and antilopine individuals of the total minimum number of bovid individuals, per site unit, is suggestive of the degree of bush cover during deposition (as crudely represented by the small trees) Solid line hominid figures express widely accepted taxonomic evaluations, dotted lines signify in the cases of KB and D16 that the presence of *Homo* is only inferred, in the case of SE that uncertainty exists as to which hominid(s) is (are) present, but that *Homo* may be included[9] Cultural associations of SKa and SE as in ref 10, of KB as in ref 1, of SKb according to Brain (unpublished), of D16 inferred Percentage cover eight trees, 51–55%, seven, 56–60% and so on, one, 86–90%, none, 91–100%


Fig 3 Changes in average body weight and in juvenile proportions from site unit to site unit Weight classes I–IV of Bovidae as defined in ref 4, all data for *a–c* from ref 3 *a*, Percentage juveniles of total minimum number of individuals in each site unit *b*, Percentage juveniles present in combined weight classes I and II (solid columns, <80 kg per individual) on the one hand, and III and IV (hatched columns, >80 kg per individual) on the other, in each site unit *c*, Estimated average weight (kg) per individual, in each site unit

assemblage among those considered in this study An hypothesis that the SE toolmaker was a scavenger would fit the available data very well If the extensively fragmented SE bovid remains were indeed the discards of meals scavenged from carnivore kills, one would not expect a high percentage of juveniles, nor an increased sampling of juveniles in higher weight categories (Fig 3*b*), although the average weight of what is consumed may still be as high as that of a primary assemblage of carnivore remains (Fig 3*c*)

The pattern presented by the bovid remains is consistent with their chronological succession In the earlier three assemblages

there is strong evidence of carnivore occupation of the Krugers-dorp caves, and such parameters as those used here agree consistently from site unit to site unit Thereafter the only evidence available here indicates (at least predominant) hominid occupation of caves in the same places that were previously dominated by carnivores Were carnivores dominant to earlier hominids, but ousted by their more advanced descendants, in the competitive search for shelter in the Sterkfontein Valley? Certainly the site units here investigated can be divided into an earlier carnivore occupation phase and a later hominid occupation phase Within the latter, the hominid quest for animal protein may have first led to scavenging, and only later to hunting If the present interpretation of bovid remains is correct, it would support the conclusion of a number of authors that tools were being fashioned before attainment of the hunting adaptation SE tools, serving to procure vegetable foods and to prepare scavenged meat, may have been the hominid pre-adaptation for the hunting which is evident in the later site units

Structural invariants in protein folding

Cyrus Chothia*

Department of Chemical Physics, The Weizman Institute of Science, Rehovot, Israel, and
MRC Laboratory of Molecular Biology, Hill, Road Cambridge, UK

An analysis of 15 protein structures indicates First, the loss of accessible surface area by monomeric proteins on folding—proportional to hydrophobic energy—is a simple function of molecular weight, second, the proportion of polar groups forming intramolecular hydrogen bonds is constant, and third, protein interiors are closely packed, each residue occupying the same volume as it does in crystals of amino acids

THE aesthetic shock of the first protein structures is expressed in Kendrew's contemporary description of myoglobin[1] as "almost nothing but a complicated set of rods [of poly-

peptide] sometimes going straight for a distance then turning a corner and going off in a new direction much more complicated and irregular than most of the early theories of the structure of proteins had suggested"

Although structural similarities between proteins of different sequence but similar functions have become apparent, the image of protein structure as a disordered and complex assembly of pieces of secondary structure has continued to the present day

At the same time as the first protein structures became known a simple qualitative theory for the energies responsible for maintaining protein structure was described, principally

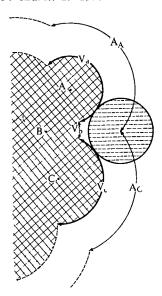
*Present address Service de Biochimie cellulaire, Institut Pasteur, 28, rue du Docteur Roux, 75015 – Paris, France


Fig 1 Two-dimensional illustrations of the concept of accessible surface area—the area over which the centre of a water molecule can be placed while retaining van der Waals' contact with that protein atom and not penetrating any other atom Three atoms, A, B, and C have the van der Waals' envelopes V_A, V_B and V_C which define the surface of the protein Atoms A and C have the accessible surface represented by the arcs A_A and A_C, A and C sterically prevent any contact between water molecule shown and atom B which therefore has no accessible surface

by Kauzmann[2] Essentially, this stated that when a protein folds the gain in hydrophobic energy, as a result of the reduction in the number of non-polar contacts with water, compensates for the loss of chain configurational entropy, and that polar groups on the interior of the protein form hydrogen bonds[3]

Here I show that, if in place of chain topology, structural descriptions are used which are directly related to energy terms—accessible surface areas, hydrogen bonds and residue volumes—there are simple equations or expressions which quite accurately describe protein structures

The atomic coordinates of 15 proteins were used lysozyme, α-chymotrypsin, insulin, rubredoxin, porcine trypsin inhibitor (PTI), high potential iron protein (HIPIP), calcium binding protein (CBP), ribonuclease S, staphylococcal nuclease, papain, concanavalin A (con A), subtilisin, thermolysin, carboxypeptidase A and lactate dehydrogenase (LDH) The

atomic coordinates of the first two proteins were energy refined by Levitt[4,5] and I carried out a preliminary energy refinement of the coordinates of the last 10

The structures of haem proteins are not described by some of the relationships derived below and will be dealt with elsewhere

Accessible surface area of proteins

The term "accessible surface area" has been introduced by Lee and Richards[6] to describe the area over which contact between protein atoms and water molecules can occur For a particular atom, this term is defined as the area over which the centre of a water molecule can be placed while retaining van der Waals' contact with that atom and not penetrating any other protein atom (Fig 1) Atomic accessible surface areas were calculated by Lee and Richards[6] for lysozyme, ribonuclease S and myoglobin, and by Shrake and Rupley[7] for lysozyme and insulin It was later shown that in proteins the hydrophobic free energies are directly related to the accessible surface area of both polar and non-polar groups[8] Here I show that the hydrophobic energy of proteins—proportional to the loss of accessible surface area that occurs on folding—is related to its molecular weight by a simple equation

In the calculations described below the following abbreviations are used

A_S, The accessible surface area of the folded native protein

A_T, The accessible surface area the protein would have if it unfolded and assumed an extended conformation with the side chains *trans*

A_B, The accessible surface area that is buried when the protein folds, equal to $A_T - A_S$

F_{AS}, The proportion of the proteins' accessible surface that is buried when it folds equal to A_B/A_T

Accessible surface areas were found using the method described by Lee and Richards[6] and a computer program written by Levitt (personal communication) Hydrogen atoms are not considered individually but included in the van der Waals' radii used for non-hydrogen atoms The van der Waals' radii used, oxygen 1 40 Å, trigonal nitrogen 1 65 Å, tetrahedral nitrogen 1 50 Å, tetrahedral carbon 1 87 Å, trigonal carbon 1 76 Å, sulphur 1 85 Å and water 1 40 Å, were based on the intermolecular contact distances observed between non-hydrogen atoms in the accurate crystal structure analysis of amino acids (Koetzle, personal communication) Accessible surface areas of individual residues, R, were calculated using the peptide Gly-R-Gly which has an extended β conformation ($\Phi = -140°$, $\Psi = 135°$) and the side chains fully extended

Table 1 Accessible surface area and proportion of polar groups forming intramolecular hydrogen bonds in 15 proteins
Protein	Molecular weight	A_T	A_S	A_B	Calculated A_B	F_{AS}	F_{HB}
Insulin*	5,787	8,380	3,440	4,940	(5,230)	0 59	0 37
Rubredoxin†	6,108	8,670	3,320	5,350	5,530	0 62	0 36
PTI	6,158	9 440	3,700	5,740	5,580	0 61	0 36
HIPIP	8,976	13,380	4,600	8,780	8,330	0 66	0 46
CBP	11,489	16,740	5,740	11,000	10,890	0 66	0 52
Ribonuclease S	13,690	19,840	6,550	13,290	13,210	0 67	0 42
Lysozyme	14,814	20,560	6,480	14,080	13,880	0 68	0 48
Staphylococcal nuclease‡	15,973	23,800	7,840	15,960	15,690	0 67	0 48
Papain	23,423	33,850	9,210	24,640	24,360	0 73	0 42
α–Chymotrypsinφ	24,608	35,900	10,130	25,770	25,820	0 72	0 44
Con A*	25,578	37,030	10,230	26,800	(27,030)	0 72	0 40
Subtilisin	27,534	40,090	9,790	30,300	29,510	0 76	0 51
Thermolysin	34,334	49,410	11,570	37,840	38,600	0 77	0 49
Carboxypeptidase	34,409	49,870	11,260	38,610	38,710	0 77	0 50
LDH*	36,470	53,080	17,060	36,020	(41,610)	0 68	0 42

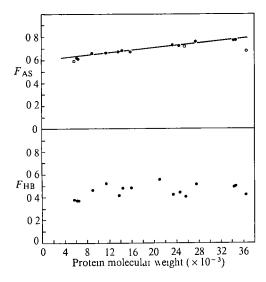
Areas are expressed in $Å^2$ Calculated A_B = the value of A_B given by equation (3) F_{AS} = the proportion of the protein's accessible surface area that is buried when it folds equal to A_B/A_T F_{HB} = the proportion of protein polar groups forming main chain–main chain or side chain–main chain hydrogen bonds
  *Calculation carried out on an isolated monomer
  †Molecular weight of the sequence found by the X-ray analysis (ref 23)
  ‡Calculations do not include the terminal residues 143–149 which are not seen in the Fourier rays
  φCalculations do not include residues 10–16 which are not seen in the Fourier map


Fig 2 upper, F_{AS}, the proportion of the potential accessible surface area a protein buries when it folds, and lower, F_{HB}, the proportion of protein polar groups forming one or more main chain–main chain or main chain side chain hydrogen bonds, plotted against protein molecular weight The F_{AS} values for oligomeric proteins are represented by open circles

($\chi_1 = -120°$, $\chi_{n+1} = 180°$) The values of residue accessible surface areas were similar to those found by Shrake and Rupley[7], though they used slightly different van der Waals' radii and averaged over a number of different residue conformations

In Table 1, the values for A_T, A_S and A_B are listed for 15 proteins A_T values were found by summing the residue accessible surface areas for each residue present in the protein

As might be expected, A_T is proportional to molecular weight (M) The expression

$$A_T = 1\ 44M \tag{1}$$

gives values in $Å^2$ within 1 % for 12 of the proteins considered and within 3 % for the rest In Fig 2a, the value of $F_{AS} = (A_B/A_T)$ is plotted against molecular weight for each protein The points on this graph can be divided into two sorts the oligomeric proteins, insulin, concanavalin A and lactate dehydrogenase,

and the rest, which are monomeric proteins with between 54 and 316 residues A least squares treatment shows that for the monomeric proteins F_{AS} is linearly related to molecular weight by the equation

$$F_{AS} = 0\ 595 + 0\ 536M \times 10^{-5} \tag{2}$$

The protein accessible surface area which is buried on folding, A_B, is $A_T \times F_{AS}$ Therefore,

$$A_B = 0\ 859M + 0\ 774M^2 \times 10^{-5} \tag{3}$$

This equation gives values for A_B in $Å^2$ to within at least 3 % of those observed (Table 1) for all the monomeric proteins Nozaki and Tanford[9] calculated, from the free energy of transfer of amino acids from water to ethanol or dioxane, the hydrophobicity values of 10 side chains, and if, in the manner described previously[8], these values are equated with the side chain accessible surface areas calculated here, it is found that for each $Å^2$ removed from contact with water there is a free energy gain of 20 calorie (the value given in ref 8 using the side chain accessible surface areas of Lee and Richards, was 24 calorie) If the transfer is from water to hydrocarbon solvents, instead of to ethanol, free energy values are about 20% higher[10] Therefore taking the hydrophobicity of amino acid residues to be 24 calorie per $Å^2$ the hydrophobic contribution to the free energy of folding, E_{HP}, in calories is (from equation (3))

$$E_{HP} = 21M + 19M^2 \times 10^{-5} \tag{4}$$

The application of equation (2) to proteins larger than those considered here is obviously limited The little information so far available (for example, refs 11–14) indicates that the structures of large globular proteins consist of quite distinct domains of a size similar to the molecules considered here and that these domains can by themselves retain a functional structure This suggests that for large globular proteins F_{AS} is essentially constant

There are three oligomeric proteins in the sample considered here insulin, con A, and lactate dehydrogenase The observed values of F_{AS} for insulin and con A, 0 59 and 0 72 respectively, are smaller, though not significantly, than the values calculated

---

Table 2 Volume occupied by residues in the interior of 9 proteins

Residue	Total no in the proteins	No buried*	Average volume (V_R) of buried residue ($Å^3$)	S D of V_R($Å^3$)	†Residue crystal volume equal to amino acid volume less 11 1$Å^3$
Val	163	91	141 7	8 4	143 4
Ala	183	71	91 5	6 7	96 6
Ile	106	69	168 8	9 8	169 7
Gly	160	60	66 4	4 7	66 5
Leu	138	57	167 9	10 2	—
Ser	190	46	99 1	7 4	102 2
Thr	128	32	122 1	6 7	124 3
Phe	60	29	203 4	10 3	—
Asp	117	17	124 5	7 7	122 0
Cys	34	16	105 6	6 0	108 7
Pro	67	16	129 3	7 3	124 4
Met	28	14	170 8	8 9	176 1
Tyr	98	13	203 6	9 6	201 7
Glu	65	13	155 1	11 4	143 9
Asn	116	12	135 2	10 1	—
Trp	39	9	237 6	13 6	—
His	43	8	167 3	7 4	166 3
Lys	119	5	171 3	6 8	—
Gln	80	5	161 1	13 0	148 0
Cyh	10	4	117 7	4 9	123 1
Arg	63	0	—	—	—

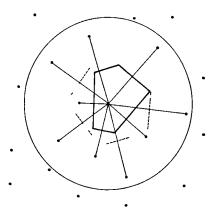
The nine proteins are CBP, ribonuclease S, lysozyme, papain, α–chymotrypsin, subtilisin, carboxypeptidase, thermolysin and LDH
*A residue is defined as buried if 5 % or less of its potential accessible surface area is available to solvent contact
†11 1 Å is the volume lost by an amino acid on becoming a residue The value used here was found by comparing the crystal volumes of glycine and glycylglycine, and is identical to the value in Cohn and Edsall[22]—11 0$Å^3$—determined by solution studies No accurate unit cell dimensions were found for Leu, Phe, Asn, Trp and Lys


Fig 3 Two-dimensional illustration of Richards' method of finding the volume occupied by an atom in a protein Vectors are made from the atom to all neighbours within a radius of 6 5 Å Planes perpendicular to each of these vectors are then constructed at a point related to the van der Waals' radii of the two atoms forming the vector The smallest polyhedron so constructed—the Voronoi polyhedron—is the volume occupied by the atom (see refs 19 and 20)

from equation (3), 0 63 and 0 73 The observed F_{AS} value for LDH, 0 68, however, is very significantly smaller than the calculated value, 0 79 Subunit contacts involve large hydrophobic free energies[9], and so these observed F_{AS} values suggest, the subunit contacts formed in oligomeric proteins may allow the subunits to have a more open structure than that found for monomeric proteins of the same size

Intramolecular hydrogen bonds in proteins

The free energy of intramolecular protein hydrogen bonds as compared with those between water and protein is unknown Experimental values for the difference in enthalpy are small[15,16] We could expect the entropy contribution to favour protein–protein hydrogen bonding as this would release bound water molecules (as occurs on the melting of ice where each molecule gains 18 e u)

Protein hydrogen bonds were found by using a computer program (Levitt, personal communication) which, given a list of non-hydrogen coordinates, adds hydrogens in positions fixed by the known stereochemistry of H–X–W bond angles and lengths, and then prints out Z–Y   H–X arrangements where Y is a hydrogen bond acceptor, H–X a donor and the geometry is satisfactory for hydrogen bond formation a hydrogen bond was accepted if the distance Y   X was 3 5 Å or less, the angle Z–Y   X more than 90°, and the angle Y   H–X more than 150°

Hydrogen bonds were listed in this way for the 15 proteins In Fig 2b the proportion of the polar groups that were found to form one or more main chain–main chain or main chain–side chain hydrogen bonds, F_{HB}, is plotted against the protein's molecular weight The precise absolute values for F_{HB} are not significant as they depend on the geometrical criteria used to determine hydrogen bonds The differences between F_{HB} values for proteins of molecular weight greater than 8,900 are not significant since the number of polar groups which correctly form hydrogen bonds depends on the quality of Fourier map and the subjection of the initial coordinates to Diamond model building, and real space, difference Fourier and energy refinement[5] This is particularly true of the few groups forming side chain–side chain hydrogen bonds For this reason and because many of them have a transient existence[17,18], they were not included

From Fig 2b, it is unambiguously clear that, for those proteins considered here that have a molecular weight over 8,900, the proportion of polar groups forming intramolecular hydrogen bonds is essentially constant and close to 0 5

For most globular proteins the number of polar groups present is proportional to molecular weight of the 15 considered here

$M/38$ 8 gives the number of polar groups to within 3 % except for lysozyme (4 %) and ribonuclease (5 %) This implies that to a good approximation the contribution of hydrogen bonds to the free energy of protein folding is simply proportional to molecular weight

Volume occupied by residues in the interior of proteins

Globular proteins are distinguished from fibrous proteins and other two-dimensional biological structures by the ability of the pieces of secondary structure from which they are formed to associate and give a stable three-dimensional structure I shall discuss briefly the nature of the molecular interactions that occur between pieces of secondary structure

The problem can be put in terms of the question how well do pieces of secondary structure recognise each other? The quantitative answer can be found by calculating the volumes occupied by residues in the protein interior Large residue volumes (low density) would imply that the recognition was poor and the association similar to that which occurs in micelles, while a small volume (high density) could mean that the recognition is precise and similar to that which occurs in crystalline solids Residue volumes are directly related to packing energies and conformational entropies
